## EXECUTIVE SUMMARY

The San Francisco Department of Public Health's Division of Population Health and Prevention has completed a comprehensive and systematic analysis of the burden of premature mortality from disease and injury experienced by residents of the City and County of San Francisco. This analysis, using methods from the World Health Organization's recent study, The Global Burden of Disease ${ }^{1}$, revealed the leading causes of death for San Francisco residents by age, sex, ethnicity, and neighborhood, showing those causes which are most important. Furthermore, we estimated how much of the burden of premature death could be prevented, if factors known to contribute to these causes of deaths were removed. Thus, this analysis provides a detailed profile of the mortality burden from disease and injury for the residents of San Francisco, and can serve to guide prevention efforts.

Using death certificates for San Francisco residents, we collected the sex, age, ethnicity, ZIP code and underlying cause of death for the six-year period 1990 through 1995. For each demographic group, we calculated the number of deaths due to each cause, and estimated how much longer people would have been expected to live had they not died of that cause. This measure, the standard expected years of life lost (SEYLL), thus provides a measure of the importance of each cause of death. The model life table standard used for this study, adapted from that used by the World Health Organization (WHO) Global Burden of Disease Study, has a life expectancy at birth of 82.5 years. The same life expectancy standard was applied to male and female deaths. We also calculated, for each demographic group, the age-adjusted mortality rates, which allowed us to compare death rates for different causes between populations composed of different numbers of older and younger people. We finally calculated the life expectancy, at different ages, of members of each demographic group, and also the expected improvement in life expectancy in the absence of a leading cause of death.

To identify and rank the leading causes of death, we used standard expected years of life lost. This measure gives greater weight to more premature deaths, which are usually more preventable. Causes of death that are more common in younger persons (e.g., unintentional injuries) tend to have higher rankings when ordered by SEYLL than by other mortality measures. The total expected years of life lost from any particular cause is then calculated by adding up the expected years of life lost for each individual who died. However, these summed SEYLL estimates cannot be used to compare various demographic groups with each other because each group has a different mix of older and younger people. To compare causes of mortality between ethnic groups, and to identify disparities between ethnic groups and between men and women, we calculated age-adjusted death rates.

Unlike many other analyses of mortality data, we not only used broad groupings of causes, such as cancer or unintentional injury, but also analyzed the data for more specific causes, such as lung cancer or suicide. More specific causes are useful for developing prevention priorities and strategies. To further the focus on prevention, we also linked specific causes of death to determinants or risk factors that are known to contribute to a large share of deaths in the U.S.

## Principal findings

## Leading causes of death

During the six-year period 1990 through 1995, there were 48424 deaths to San Francisco residents or occurring in San Francisco to persons of unknown residence (1066 deaths). These deaths represented a total of 1.07 million standard expected years of life lost. Overall and for males, AIDS was the leading cause of premature mortality, followed by ischemic heart disease, lung cancer, stroke, and drug poisoning (Figure 1, p. 2). For females, ischemic heart disease was the leading cause of death, followed by stroke, lung cancer, breast cancer, and pneumonia.

The key findings were the following:

- AIDS was by far the leading cause of death overall and among men (Figure 1). 6832 San Francisco residents died from AIDS, representing 300755 standard expected years of life lost (Table 1). Male mortality from AIDS numbered 6650 deaths and 292636 standard expected

[^1]

Figure 1: Standard Expected Years of Life Lost (SEYLL) from the 13 Leading Causes of Death, San Francisco 1990-1995
years of life lost; this was more than all the expected years of life lost for females from all causes (Figure 1; Table 16, p. 40). AIDS was the first leading cause of death among White, Latino, African-American, and Native American males and second among Filipino males (Table 45, p. 74). Female deaths from AIDS numbered 182 and represented 8119 standard expected years of life lost (Table 16, p. 40). AIDS was the sixth leading cause of death for females, and the second leading cause for African-American and Latino females. In every San Francisco neighborhood, AIDS was the first or second leading cause of male deaths (Table 18, p. 42). The transmission category for the majority of AIDS cases in San Francisco has been men having sex with men, with the next largest category being injecting drug users.

- Ischemic heart disease, the leading cause of death in California and the United States, was the second leading cause of death overall (Figure 1): 11010 San Francisco residents died from ischemic heart disease, representing 141184 standard expected years of life lost (Table 1). Among males, ischemic heart disease was the second leading cause of death; it was the first or second leading cause in every neighborhood (Table 47, p. 83) and for each ethnic group except Latinos, among whom it ranked third (Table 45, p. 74). Among females, ischemic heart disease was the leading cause of death overall, for every ethnic group (Table 45), and for every neighborhood (Table 48, p. 84). Tobacco smoking, diet and physical inactivity are major determinants of
ischemic heart disease.
- Lung cancer was the third leading cause of death overall and for both males and females: 2455 San Francisco residents died from lung cancer, representing 45351 standard expected years of life lost (Table 1). Among males, lung cancer ranked second for Asians, fourth for Filipinos, and fifth for Whites and African-Americans; it was among the top five causes of death in 16 of 22 neighborhoods, and among the top ten causes in every neighborhood (Table 47, p. 83). Among females, lung cancer ranked second for Whites, third for Asian/Pacific Islanders, and fourth for African-Americans; it was among the top five causes of death in 20 neighborhoods, and among the top ten causes in every neighborhood (Table 48, p. 84). More than $85 \%$ of lung cancers are attributable to tobacco smoking.
- Stroke was the fourth leading cause of death overall (Figure 1), the second leading cause among females, and the seventh leading cause among males: 3374 San Francisco residents died from stroke, representing 41182 standard expected years of life lost (Table 1). Stroke was a leading cause among all ethnicities, ranking second or third among females, and among the top nine for males (Table 45, p. 74). Stroke was among the top six causes of death in 13 neighborhoods for males and in all 22 for females (Tables 47-48, pp. 83-84). Tobacco smoking, diet, and physical inactivity are important determinants of stroke.
- Drug poisoning was the fifth leading cause of death overall (Figure 1), the fourth leading cause among males, and the tenth leading cause among females: 735 San Francisco residents died from drug poisoning, representing 33023 standard expected years of life lost (Table 1). Among African-American, Latino, Native American, and White males, drug poisoning was the third or fourth leading cause of death (Table 45, p. 74). Among African-American and White females, it was the sixth and ninth leading cause of death respectively. Drug poisoning was the third or fourth leading cause of male death in ZIP codes 94102 (Hayes Valley, Tenderloin, North of Market), 94103 (South of Market), 94107 (Potrero Hill), 94110 (Inner Mission, Bernal Heights), 94117 (Haight-Ashbury), and 94124 (Bayview-Hunters Point) (Table 47, p. 83). Drug poisoning was the second or third leading cause of female death in ZIP codes 94102, 94103, and 94107 (Table 48, p. 84). Almost all drug poisoning deaths were illicit drug overdoses.
- Suicide was the sixth leading cause of death overall (Figure 1), the fifth leading cause among males, and the ninth leading cause among females: 845 San Francisco residents died from suicide, representing 32729 standard expected years of life lost (Table 1). Among males, suicide was the third leading cause of death among Whites, the sixth leading cause among Latinos, and the seventh leading cause among Asian/P.I. (Table 45, p. 74). Among females, suicide was the seventh leading cause of death among Whites and Asian/P.I. Suicide was the third leading cause of male death in ZIP codes 94108 (Chinatown), 94109 (Polk \& Russian Hills), 94114 (Castro, Noe Valley), 94117 (Haight-Ashbury), and 94131 (Twin Peaks-Glen Park); it was among the top nine causes in all but one neighborhood (Table 83, p. 83). Suicide among females was ranked fifth or higher in ZIP code 94104/05/11 (Rincon, Telegraph Hill, Embarcadero), 94121 (Outer Richmond), and 94131 (Twin Peaks-Glen Park); it was among the 10 leading causes in 12 of 22 neighborhoods (Table 48, p. 84). Alcohol, firearms and illicit drugs are contributing factors for suicides.
- Homicide was the seventh leading cause of death overall (Figure 1), the sixth leading cause among males, and the 16th leading cause among females: 557 San Francisco residents died from homicide, representing 28571 standard expected years of life lost (Table 1). Homicide was the second and third leading cause of death among Latino and African-American males, respectively (Table 45, p. 74). Among females, homicide was the seventh and ninth leading cause of death among African-Americans and Latinos, respectively. In Bayview-Hunters Point (ZIP code 94124), homicide was the leading cause of male death; it was the third or fourth leading cause of male death in ZIP codes 94107 (Potrero Hill), 94110 (Inner Mission, Bernal Heights), 94112 (Ingleside-Excelsior, Crocker-Amazon), 94115 (Western Addition, Japantown), and 94134 (Visitación Valley, Sunnydale) (Table 47, p. 83). Homicide was the fifth and sixth leading cause of female death in ZIP codes 94103 (South of Market) and 94124 (Bayview-Hunters

Point), respectively (Table 48, p. 84). Firearms, alcohol and illicit drugs are contributing factors for homicides.

## Racial/ethnic disparity

There were marked racial disparities in age-adjusted all-cause and cause-specific mortality rates:

- All-cause mortality rate trends by ethnicity were evaluated for the nine-year period 1987 through 1995 (Figure 5, p. 26). African-American all-cause mortality rates were, by far, the highest for both sexes. Whites had the next worst mortality, with Latinos and Asians/others having the lowest all-cause mortality rates in San Francisco. The trends showed a moderate mortality rate decline over the period for African-American and White males and for females. In spite of the moderate improvements for each group over this nine-year period, the racial/ethnic disparity mortality rates did not appear to narrow.
- Life expectancy is another, more intuitive, measure of today's mortality burden from all causes. Calculated from mortality data from the study period 1990 through 1995 (Table 11, p. 30), African-Americans had the lowest life expectancy, with the disparity between ethnic groups greater among males than females. San Francisco African American male life expectancy at birth was 60.0 years, which was lower than the 1993 U.S. African American male life expectancy at birth of 64.6 years. This is the lowest life expectancy for African American males in 25 years (1970 U.S. African American male life expectancy was 60.0 years). In contrast, U.S. White males have not had a life expectancy this low since 1940 ( 62.1 years). San Francisco White males had the next lowest life expectancy of 64.9 years; this is much lower than the 1993 U.S. White male life expectancy of 73.1 years. The highest life expectancies were for Latino females (87.9 years) and Asian/other females (84.6 years).
- For the period 1990 through 1995, age-adjusted mortality rates were calculated for the 13 overall leading causes of death, which included the top ten causes for males and females (Figures 6-7 and Tables 9-10, pp. 28-29). For males and females, African American age-adjusted mortality rates were the highest for almost every leading cause of death. With the exception of AIDS and suicide (where White males had the highest rates), African-American males had the highest mortality rates among the four ethnic groups for 10 of the 12 leading causes of death in San Francisco. Their mortality rates were significantly higher than the other groups for six of the top eight causes (ischemic heart disease, lung cancer, stroke, drug poisoning, homicide, and pneumonia). African-American females had the highest mortality rates among females for 10 of the 13 leading causes of death, all except for suicide, chronic obstructive pulmonary disease, and motor vehicle-traffic deaths. Their mortality rates were significantly higher for five of the seven leading causes (AIDS, ischemic heart disease, stroke, drug poisoning, and homicide) and breast cancer.

## Sex differences

- Mortality was much greater for males than females overall, within each ethnic group and for all the leading causes of death except stroke and breast cancer (Figures 1; 5, p. 26). Males had 2.7 times as many expected years of life lost as females, and, even without the enormous burden of premature mortality among males due to AIDS, males had 1.7 times as many expected years of life lost as females.

## Age differences

From 1990 through 1995, leading causes of deaths varied significantly by age group (Tables 13-15, pp. 34-36):

- 362 infants less than one year died (average of 60 per year), representing 29865 expected years of life lost. Sudden Infant Death Syndrome (SIDS) was the leading cause of infant death: 85 deaths and 7012 expected years of life lost. SIDS was followed by congenital anomalies ( 70 deaths, 5775
expected years of life lost), and birth asphyxia \& trauma (43 deaths, 1155 expected years of life lost). Four infants died from homicide and three died from AIDS.
- 72 infants/toddlers, ages one to four, died (average of 12 per year), representing 5892 expected years of life lost. In this age group congenital anomalies was the leading cause of death (16 deaths, 1309 expected years of life lost), followed by homicide ( 7 deaths, 573 expected years of life lost), motor vehicle-traffic accidents (5 deaths, 409 expected years of life lost), and fires (4 deaths, 327 expected years of life lost).
- 76 children, ages 5 to 14 years, died (average of 13 per year), representing 5726 expected years of life lost. In this age group motor vehicle-traffic accidents were the leading cause of death ( 15 deaths, 1130 expected years of life lost), followed by congenital anomalies ( 8 deaths, 594 expected years of life lost), homicide ( 7 deaths, 521 expected years of life lost), and leukemia (5 deaths, 385 expected years of life lost).
- 517 young adults, ages 15 to 24 years, died (average of 86 per year), representing 33329 expected years of life lost. In this age group homicide was the leading cause of death ( 157 deaths, 10180 expected years of life lost), followed by suicide ( 79 deaths, 5067 expected years of life lost), motor vehicle-traffic accidents ( 78 deaths, 5024 expected years of life lost), AIDS ( 30 deaths, 1892 expected years of life lost), and drug poisoning ( 22 deaths, 1398 expected years of life lost).
- 8110 adults, ages 25 to 44 years, died (average of 1352 per year), representing 394595 expected years of life lost. In this age group AIDS was the leading cause of death ( 4640 deaths, 224627 expected years of life lost), followed by drug poisoning ( 506 deaths, 25035 expected years of life lost), suicide ( 350 deaths, 17534 expected years of life lost), homicide ( 264 deaths, 13821 expected years of life lost), and chronic liver disease (189 deaths, 8952 expected years of life lost).
- 8845 adults, ages 45 to 64 years, died (average of 1474 per year), representing 279156 expected years of life lost. In this age group AIDS was the leading cause of death (2 031 deaths, 71666 expected years of life lost), followed by chronic conditions for which mortality increases greatly with aging: ischemic heart disease, lung cancer, chronic liver disease, and stroke.
- 30339 older adults, aged 65 years or older, died (average of 5057 per year), representing 319646 expected years of life lost. The leading cause of death was ischemic heart disease, followed by stroke, lung cancer, pneumonia, and COPD.

Homicide was between the first and seventh leading cause of death in each age group from birth through 44 years. AIDS was between the first and eighth leading cause of death in every age group from birth through 64 years. Motor vehicle-traffic accidents were between the first and sixth leading cause of death in every age group from 1 through 44 years.

Breast cancer was between the second and sixth leading cause of death for females in all age groups from 25 years or older (Table 15, p. 36). In contrast, prostate cancer, an exclusively male cancer, was as high as the sixth leading cause of death only for males 65 years or older (Table 14, p. 35).

## Linking causes of deaths to underlying determinants

Identification and ranking of the leading causes of premature deaths is insufficient data for prevention planning; true underlying causes or determinants must be identified and measured. Based on this approach, more than half of the deaths in the United States in 1990 were attributed to nine wellknown determinants (also called contributing factors or causal risk factors) ${ }^{2}$ : tobacco use, diet and physical inactivity, alcohol consumption, infectious agents, environmental toxins, firearms, unsafe sex, motor vehicles, and illicit drugs. People to whom a given causal risk factor applies (who may be said to be exposed to that causal risk factor) have an increased risk of disease or death. To quantitatively link these nine determinants to the leading causes of premature death in San Francisco, we created prevention attribution matrices based on an extensive review of the biomedical and public health

[^2]Table 1: Leading Causes of Death and Prevention Attribution Matrix, All Residents 1990-1995

| Specific Cause of Death | SEYLL | \% | Count | \% | $\begin{aligned} & \mathrm{T} \\ & \mathrm{O} \\ & \mathrm{~B} \\ & \mathrm{~A} \\ & \mathrm{C} \\ & \mathrm{C} \\ & \mathrm{O} \end{aligned}$ | D <br> I <br> E <br> T <br> E <br> X <br> E <br> R <br> C | $\begin{gathered} \mathrm{A} \\ \mathrm{~L} \\ \mathrm{C} \\ \mathrm{O} \\ \mathrm{H} \\ \mathrm{O} \\ \mathrm{~L} \end{gathered}$ | $\begin{gathered} \mathrm{I} \\ \mathrm{~N} \\ \mathrm{~F} \\ \mathrm{E} \\ \mathrm{C} \\ \mathrm{~T} \\ \mathrm{I} \\ \mathrm{O} \\ \mathrm{U} \\ \mathrm{~S} \\ \hline \end{gathered}$ | $\begin{gathered} \mathrm{E} \\ \mathrm{~N} \\ \mathrm{~V} \\ \mathrm{~V} \\ \mathrm{I} \\ \mathrm{R} \\ \mathrm{O} \\ \mathrm{~N} \\ \mathrm{M} \\ \mathrm{E} \\ \mathrm{~N} \\ \hline \hline \end{gathered}$ | $\begin{gathered} \mathrm{F} \\ \mathrm{I} \\ \mathrm{R} \\ \mathrm{E} \\ \mathrm{~A} \\ \mathrm{R} \\ \mathrm{M} \\ \mathrm{~S} \end{gathered}$ | $\begin{aligned} & \mathrm{S} \\ & \mathrm{E} \\ & \mathrm{X} \\ & \mathrm{U} \\ & \mathrm{~A} \\ & \mathrm{~L} \\ & \\ & \mathrm{E} \\ & \mathrm{X} \\ & \mathrm{P} \\ & \hline \end{aligned}$ | M <br> O <br> T <br> O <br> R <br> V <br> E <br> H <br> I | $\begin{gathered} \mathrm{D} \\ \mathrm{R} \\ \mathrm{U} \\ \mathrm{G} \\ \mathrm{~S} \end{gathered}$ |

- Attributable fraction $10 \%$ to $40 \%$
- Attributable fraction $2 \%$ to $10 \%$
* Protective effect of alcohol consumption
? More than two studies but no consensus
literature (Table 1). Many of these causal risk factors contribute to more than one cause of death, and many causes of death have more than one of these determining factors contributing to them.

The more preventable deaths are attributable to a particular causal risk factor, the more important it is to reduce exposure to that risk factor among the population. For important causal risk factors, we want to know how much of the burden of premature mortality could be prevented if this causal risk factor were somehow eliminated from the population, which is called the population attributable fraction of that determinant. To compute the population attributable fraction for a determinant, we must first calculate how much of the population is exposed to that determinant, and then what increased risk of death results from exposure to that determinant. For example, if lung cancer death rates are ten times higher in tobacco smokers compared to non-smokers (relative risk $=10$ ) and $40 \%$
of the population smokes, then the proportion of lung cancer deaths attributable to smoking is about $80 \%$, using a widely-employed calculation method ${ }^{3}$.

The results, showing the approximate share of mortality in San Francisco attributable to the nine well-known causal risk factors listed at the beginning of this section, are shown for all residents (Table 1) and by sex (Tables 6-7, pp. 24-25). For some of the cause of death/determinant intersections shown in the prevention attribution matrices (e.g., AIDS \& unsafe sex, tobacco \& lung cancer, tobacco \& heart disease, or alcohol \& homicide) fairly precise estimates of attribution can be made. For others, we use the published literature to estimate ranges of attribution: over $40 \%, 10 \%$ to $40 \%, 2 \%$ to $10 \%$.

In San Francisco, for the six-year period 1990 through 1995, the following results were apparent from this analysis:

- Unsafe sexual practices were among the leading contributing factors to preventable mortality, due to the enormous impact of AIDS deaths on premature mortality.
- Tobacco and alcohol were major contributors to premature mortality; they were responsible for about one-fifth of all deaths and all expected years of life lost (Table 19, p. 43; and Table 28, p. 53).
- Tobacco was associated with five of the ten leading causes of premature death: ischemic heart disease, lung cancer, stroke, pneumonia, and chronic obstructive pulmonary disease (Table 1).
- Alcohol was associated with six of the ten leading causes of premature death: stroke, drug poisoning, suicide, homicide pneumonia, and chronic liver disease; it is also associated with 13 of the leading 20 causes (Table 1).
- Illicit drug use was associated with six of the ten leading causes of premature death; it was a major contributor directly through drug poisoning and indirectly by contributing to other causes including AIDS, stroke, suicide, homicide, and chronic liver disease (Table 1). Drug poisoning itself was the fourth leading cause of premature mortality among males, tenth among females and fifth overall (Tables 5-7, pp. 23-25).
- Diet and physical inactivity were important contributors to premature mortality, through their role in causing a share of fatal heart disease, stroke, and colorectal and breast cancer. Diet and inactivity are associated with 2 of the 10 leading causes of premature mortality, and 7 of the top 20 (Table 1).

## Comments

The mission of the San Francisco Department of Public Health is to protect and promote the health of all San Franciscans. This report is a comprehensive, systematic, and population-based approach to the analysis of existing mortality data; it provides essential information to inform, guide, and monitor actions undertaken to improve population health. The primary measure, standard expected years of life lost, gives greater weight to deaths that occur at younger ages and allows ranking by objective criteria; it is, therefore, our preferred indicator of preventable, premature deaths. We conducted analyses not only by sex, race/ethnicity, and age, but also by neighborhood. This report allows different demographic groups, neighborhoods, and the Department of Public Health to determine what are the leading specific causes of preventable, premature deaths in diverse communities, and should help to guide community health priority setting and targeted interventions. These analyses will be repeated on a periodic basis in order to monitor changes in the mortality burden from disease and injury in all San Francisco communities.

Knowledge of the leading causes of premature deaths is, by itself, not sufficient to prevent the occurrence of disease and injury. Nevertheless, if we are to design cost-effective strategies to prevent and control disease and injury, we must first measure and rank the leading causes of disease and injury, identify the underlying determinants of these causes of disease and injury (Table 1), calculate the contribution of these determinants to the leading causes of death, and finally assess the distribution

[^3]

Figure 2: Multiple determinants of health model. (Adapted from Evans, R.G., et al. [eds.] Why Are Some People Healthy and Others Not? The Determinants of Health of Populations [New York: Aldine de Gruyter] Copyright © 1994, Walter de Gruyter Inc., New York)
of these determinants in our population. With these facts, the health model shown in Figure 2 can be used to guide, plan, and monitor improvements in population health, making the best use of this disease and injury mortality data. Disease and injury are shown in the middle of the diagram, along with health and medical care; well-being and prosperity are shown at the bottom, and environmental influences at the top. The more we can understand how the experience of our residents in the dimensions shown in the middle and bottom of the model are influenced by the factors at the middle and top of the model, the better we will be able to develop policies that protect, preserve, and promote population health and well-being.

Thus, the model in Figure 2 illustrates the fact that exposures to many determinants of disease and injury are influenced, in particular, by the social environment; in many cases, changes in social conditions may have many beneficial effects on community health. For example, laws to reduce exposures to second-hand tobacco smoke, to limit cigarette advertising, or to permit the provision of clean needles and syringes to injection drug users, not only saves lives, they improve health and quality of life. Further, social conditions affect individuals' access to educational, social, and health resources. Increasing access to such resources could provide substantial benefits to the health of many individuals, especially to those who have the least access due to socioeconomic disadvantage.

Indeed, socioeconomic conditions, especially poverty, adversely influence many health outcomes, including almost all of the leading causes of death. Other aspects of the social environment also have wide-ranging influences on many health outcomes, such as the availability of social support. Furthermore, individuals who experience substantial stress in their social environment are also at increased risk of poor health. Improving these social conditions, especially for the most vulnerable segment of the population, could be expected to provide the most widespread improvement in health and well-being. Thus, efforts to improve community health should not to be limited to clinical or behavioral interventions, but should also aim for long-term change in the social and physical environments in which we live. We hope that the results presented in this report will help diverse communities, separately and together, to set priorities and advocate for changes that improve their health.

This report links causes of death responsible for the greatest burden of premature mortality in San Francisco to nine well-established determinants that contribute to mortality from multiple specific causes of death. The prevention attribution matrix (Table 1) is our evidenced-based attempt to make these critical linkages, to guide new prevention efforts, and to target monitoring of expected outcomes.

The prevention attribution matrix for the City's overall leading causes of premature mortality can indicate the extent to which prevention efforts directed at reducing exposure to the determinants covered in this report could affect the burden of mortality from the leading causes for the City as a whole or for communities where prevention might be targeted. Primary prevention strategiesaimed at preventing the occurrence of disease or injury in the first place - that accomplish long-lasting change in the distribution of risk factors (e.g., smoking prevalence) can continue to improve population health generations into the future. The analysis provided by this report helps provide a basis to effectively protect, preserve, and promote community health-to invest in targeted strategies that improve population health today and into the future.

## 1 INTRODUCTION

The San Francisco Department of Public Health's Division of Population Health and Prevention conducts the essential function of assessing the general health of San Francisco residents. Our primary goal is to profile the health and health needs of the whole population and its communities; our first objective has been the analysis of population-based health data. Health is not just the absence of disease; however, its measurement must include the obvious impacts of disease and injury, and the distribution of the underlying factors which result in disease and injury. The most severe health impact is, of course, death, and this first comprehensive assessment covers deaths. Our specific aim was to measure and prioritize the overall and cause-specific burden of disease and injury conditions by their most severe health impacts, namely premature deaths as measured by years of life lost. Studies on the burden and distribution of non-fatal outcomes that result in temporary or permanent disabilities and that detract from the quality of life are the subjects of future reports.

In addition to reporting on the burden of mortality by cause for various population groups, we also seek to understand mortality patterns in terms of the known contributing factors or determinants that lead to premature death. Uncovering the contributions of these determinants to the burden of mortality can help guide the planning of primary prevention to effectively reduce that burden. We focus on important health outcomes whose distribution we want to understand in order to work effectively with communities to reduce their burden of injury, illness and death. Determinants in the social and physical environments influence individual and group behaviors and responses which, through a complex set of pathways, result in disease and injury and shape a population's health and well-being. A useful health model that summarizes the influence of multiple determinants on multiple outcomes is depicted in Figure 3, p. 12. This and subsequent population health assessment reports are guided by the following understanding: the more we can understand how the factors at the top and middle of the model influence the experience of our residents in the dimensions shown in the middle and bottom of the model, the better we will be able to develop policies that protect, preserve, and promote population health and well-being.

The most severe impact on health and function is a premature death. In this report we analyzed of the mortality burden of disease and injury by measuring the expected years of life lost from specific causes of death. Consistent with our health model, well-established determinants or contributing factors for the leading causes of death were reviewed to guide the planning of primary prevention. Data on non-fatal outcomes resulting in temporary or permanent disabilities that can be used to construct measures of morbidity will be analyzed later.

Department of Public Health population health assessments are intended to be used not only by the Department, but also by community organizations, advocates, and residents to make more informed decisions about the health needs and priorities of San Francisco's diverse populations. This project thus involves not only the process of developing and interpreting a whole-population picture of health status and needs, but also of incorporating such health data throughout the Department in planning and decision-making. This report specifically measures the mortality burden of disease and injury for San Francisco residents for the period 1990 through 1995 and has the following purposes:

1. To objectively, systematically, and comprehensively assess the mortality component of the overall burden of disease and injury for San Francisco residents.
2. To utilize measures that allow ranking of population disease and injury indicators for the purposes of developing public health priorities.
3. To apply what is known about factors contributing to causes of death to S.F. mortality data in order to measure the extent to which premature deaths are caused by known preventable factors.
4. To inform Division of Population Health and Prevention policy and to guide health protection, health promotion, and disease and injury prevention and control efforts.

The mortality analyses in this report are modeled, in part, after the Global Burden of Disease and Injury Series published by the World Health Organization (WHO) and the Harvard School of Public Health [38]. The primary objectives of that study were (1) ". . . to facilitate the inclusion of nonfatal health outcomes in debates on international health policy," (2) ". . . to decouple epidemiologic

Figure 3: Multiple determinants of health model. (Adapted from Evans, R.G., et al. [eds.] Why Are Some People Healthy and Others Not? The Determinants of Health of Populations [New York: Aldine de Gruyter] Copyright © 1994, Walter de Gruyter Inc., New York)
assessment from advocacy so that estimates of the mortality or disability from a condition are developed as objectively as possible," and (3) ". . . to quantify the burden of disease using a measure that could also be used for cost-effectiveness analysis." Based on these objectives, these investigators developed Disability Adjusted Life Years (DALY) as their primary measure. DALY is calculated by summing Years Lived with Disability (YLD) and Standard Expected Years of Life Lost (SEYLL). YLD measures the population burden of non-fatal health outcomes and is not the subject of this report. The measure of the population burden of fatal outcomes is SEYLL, and it is the primary measure used in this report.

This report is a comprehensive, systematic and population-based approach to the analysis of San Francisco mortality data. The primary measure, SEYLL, gives greater weight to deaths that occur at younger ages and is therefore our preferred indicator of preventable, premature deaths. Our cause of death classification system was modified from the WHO Global Burden of Disease (GBD) Study and made particularly relevant to San Francisco (Table 2, p. 15). Analyses were conducted not only by sex, race/ethnicity, and age, but also by neighborhood. This report summarizes for the San Francisco Department of Public Health and community residents the leading specific causes of premature, preventable deaths in their communities, and should help to guide health priority setting and targeted interventions. These analyses will be repeated on a periodic basis for the purposes of monitoring changes in the mortality burden of disease and injury in all San Francisco communities.

## 2 METHODS

### 2.1 Data source

The Public Health Information System (PHIS) summary death certificate data for the years 1990 through 1995 were obtained from the Data Retrieval and Analysis Section of the California Department of Health Services. These summary data included all certified deaths of San Francisco residents regardless of where they died, as well as people dying in San Francisco but with no known residence. The data file included variables for sex, race/ethnicity, age, age group, code for underlying cause of death, and ZIP code of residence. Codes for underlying cause of death were from the International Classification of Diseases, 9th Revision (ICD-9). The race/ethnicity variable had 7 categories available across all 6 years: White, African American, Latino, Asian/Pacific Islander, Filipino, Native American, and Other.

### 2.2 Mortality measures

For the period 1990 through 1995, the following were determined for all San Francisco residents, for San Francisco residents stratified by race/ethnicity, and for San Francisco residents stratified by ZIP code: (1) Mortality count by total, by sex, and by sex and age, and (2) Standard Expected Years of Life Lost (SEYLL) by total, by sex, and by sex and age. We used SEYLL as our base measure of mortality, because it incorporates a weighting for degree of prematurity of deaths, and because it can be calculated for neighborhoods in the absence of reliable, timely population information needed to compute rates. All rankings by specific causes of death presented in this report are based on SEYLL .

Standard expected years of life lost is defined as follows:

$$
S E Y L L=\sum_{x=0}^{l} d_{x} e_{x}^{*}
$$

where $d_{x}$ is the number of deaths at age $x$ and $e_{x}^{*}$ is the expectation of life at each age $x$ based on some ideal standard. For this report, the standard used for male and female deaths was based on a model life table from Coale and Demeny West Level 26 which has a life expectancy at birth for females of 82.5 years. We chose this life table standard as achievable by San Francisco residents and because it was used by the Global Burden of Disease study.

For the period 1990 through 1995 and for the consecutive the three-year periods 1987 through 1989, 1990 through 1992, and 1993 through 1995, age-adjusted mortality rates were calculated using the 1940 U.S. standard million population [3]. Standard methods were used to calculate confidence intervals [6]. Population estimates and projections used in the calculation of mortality rates were obtained from the California Department of Finance Demographic Research Unit. These were available for four race/ethnic categories (White, African American, Latino, and Asian/other), so rates by ethnicity were calculated for these four groupings. Life expectancies were calculated based on standard methods $[14,54]$. All analyses, including graphics, were conducted in S-Plus [34].

### 2.3 Cause of death classification

The San Francisco Department of Public Health Burden of Disease and Injury Study (SFDPH BDIS) cause of death classification is based on the WHO GBD Study with several modifications to make it more relevant to San Francisco (Table 2). Whenever possible, ICD-9 codes were modified to make the categories comparable to the Healthy People 2000 and/or National Center for Health Statistics cause of death classification. The SFDPH BDIS cause of death classification is broken down into four major aggregate levels (Level 1 category). Each sublevel (Levels 2, 3, 4) is a subset of the previous level and provides more specific, disaggregated causes of death. Level 1 categories are the following:

## I. Communicable diseases

II. Maternal-Perinatal-Nutritional conditions
III. Noncommunicable diseases
IV. Injuries

However, for more specific causes of death one could then look a Level 2, 3, or 4 category cause of death. For example, for injuries:

IV. Injuries<br>A. Unintentional injuries<br>1. Motor vehicle-traffic<br>a. Occupant<br>[Level 1 category]<br>[Level 2 category - subset of IV]<br>[Level 3 category - subset of IV.A]<br>b. Motorcyclist<br>c. Pedalcyclist<br>d. Pedestrian<br>2. Poisonings<br>a. Drug poisonings<br>3. Falls<br>4. Drowning

For each Level, number of deaths, deaths rates, and standard expected years of life lost were calculated. However, all leading causes of death listed in this report were based on specific rather than more general or aggregated causes. Specific causes are more useful for determining etiology and planning prevention actions. Mutually exclusive, but not exhaustive, categories of specific causes are shown with asterisks in Table 2.

### 2.4 Attribution

More than half of the deaths in the United States in 1990 were attributed to nine well-known determinants (or causal risk factors) [35]: tobacco use, diet and physical inactivity, alcohol consumption, infectious agents, environmental toxins, firearms, unsafe sex, motor vehicles, and illicit drugs. Individuals to whom a given causal risk factor applies (who may be said to be exposed to that causal risk factor) have an increased risk of disease or death. Moreover, many of these causal risk factors contribute to more than one cause of death. To quantitatively link these nine determinants to the leading causes of premature death in San Francisco, we created prevention attribution matrices based on an extensive review of the biomedical and public health literature (Tables 5-7, pp. 23-25).

The more preventable deaths attributable to a particular causal risk factor, the more important it is to reduce exposure to that risk factor among the population. For the nine important causal risk factors given in the previous paragraph, we wanted to know how much of the burden of premature mortality could be prevented if this causal risk factor were somehow eliminated from the population; specifically, we estimated the population attributable fraction of each determinant. To compute the population attributable fraction for each determinant, we must first calculate how much of the population is exposed to that determinant, and then what increased risk of death results from exposure to that determinant. For example, if lung cancer death rates are ten times higher in tobacco smokers compared to non-smokers (relative risk $=10$ ) and $40 \%$ of the population smokes, then the proportion of lung cancer deaths attributable to smoking is about $80 \%$, using a widely-employed calculation method [22].

Because the leading 20 causes of death differ by gender, ethnic group, and neighborhood, the matrix upon which Tables 5-7 are based encompasses the 37 leading causes of death. The resulting 37 by 9 matrix contains 333 causes of death/determinant pairs, whose potential relationships are being evaluated in steps. First, textbooks, expert opinion and MEDLINE searches were used to establish whether there is a known association between the leading causes of death and each of these determinants. Next, we evaluated, even if only roughly and approximately, the relative importance of the risk factors to each cause of death. Finally, in an ongoing process, we are conducting MEDLINE searches to find data on relative risk and prevalence from comparable populations to estimate the fraction (proportion) of deaths attributable to the contributing factors. For tobacco and alcohol, we used attributable mortality fractions from California and U.S. reports and applied them locally to estimate tobacco and alcohol attributable mortality in San Francisco (Tables 19-28, pp. 43-53).

The current depiction of levels of attribution should be considered a work in progress. We want to apply as much as possible of what is known about the factors contributing to the burden of disease and injury to local data - even if we cannot be as exact as we would like to be in establishing quantitatively

Table 2: SFDPH Burden of Disease and Injury Classification System

| Disease Classification | ICD-9 Codes |
| :---: | :---: |
| I. Communicable diseases | $001-139,320-322,381-382,460-466,480-487,$ 614-616 |
| A. Infectious \& parasitic | 001-139, 320-322, 614-616 |
| 1. Tuberculosis* | 010-018, 137 |
| 2. Sexually transmitted (\& PID)* | 090-099, 614-616 |
| 3. HIV infection/AIDS* | 042-044 |
| 4. Diarrheal diseases* | 001, 002, 004, 006-009 |
| 5. Child-cluster diseases* | 032, 033, 037, 045, 055, 056, 138, 771.3 |

[^5]the burden of mortality attributable to major contributing factors - so that this information can be drawn on for public health planning. Although our current version of the cause-contributing factor attribution table may wind up being modified over time, it also conveys much information that will be useful to planners and community groups now.

To depict the approximate levels of population attributable risk, the following symbols were applied:

- Attributable fraction greater than $40 \%$
- Attributable fraction 10 to $40 \%$
- Attributable fraction 2 to $10 \%$
* Protective effect of alcohol consumption

We again note that these are our best current estimates based on review of the literature $[1,2$, $4,5,7,8,9,10,11,12,13,15,16,18,20,19,21,23,24,26,28,29,31,32,33,35,36,37,39,40$, $41,42,43,44,45,46,47,49,50,51,52,53,55,56,57]$ but often made in the absence of the most appropriate information on strength of risk and actual distribution of determinants in populations like those comprising San Francisco ${ }^{4}$. We expect quantitative classification of some attribution table cells may change with further information and analysis, and invite interested readers to contribute their thoughts and information to the ongoing process of refining our attributable fraction estimates.

[^6]
## 3 RESULTS

The results are presented in the following sections:
3.1. Leading causes of death
3.2. Burden of AIDS deaths
3.3. Burden of tobacco consumption
3.4. Burden of alcohol and illicit drug consumption
3.5. Burden of deaths related to diet and physical inactivity
3.6. Ethnicity profiles
3.7. Neighborhood profiles

Section 3.1 summarizes the leading specific causes of death for San Francisco residents overall, by ethnicity, by sex, and by age category. This section also examines racial disparities with special focus on African Americans. Because of San Francisco's unprecedented and enormous burden of AIDS deaths, Section 3.2 is the only section dedicated to a single etiology - AIDS deaths from infection with the Human Immunodeficiency Virus (HIV). Sections 3.3, 3.4, and 3.5, summarize the group of causes of deaths in which a significant proportion of deaths can be attributed to tobacco consumption; alcohol or illicit drug consumption; or diet and physical inactivity, respectively. Section 3.6 summarizes the leading causes of death for seven race/ethnic groups: African American, Asian/Pacific Islander, Filipino, Latino, Native American, and White. Finally, Section 3.7 summarizes the leading causes of death for San Francisco neighborhoods as defined by United States Postal ZIP codes.

### 3.1 Leading causes of death

### 3.1.1 Overview

The number and percent of deaths by sex and age group for the four major cause of death categories are shown in Table 3. There were a total of 48424 deaths during the six-year period 1990 through 1995 , an average of 8070 deaths per year. Of these, 28613 , or $59.0 \%$, occurred among males. Overall, 34704 deaths ( $71.7 \%$ ) were due to non-communicable diseases, distributed almost equally between males $(50.5 \%)$ and females ( $49.5 \%$ ). In contrast, 9873 deaths ( $20.4 \%$ ) were due to communicable diseases; however, of these, the 8284 male deaths ( $29 \%$ of all male deaths) were more than five times the 1589 female deaths ( $8.0 \%$ of all female deaths) . Likewise, of the $3445(7.1 \%)$ injury deaths, the 2563 male deaths ( $9 \%$ of all male deaths) were almost three times the 882 female deaths $(4.5 \%$ of all female deaths). The proportion of deaths from communicable diseases peaks in the 25-44 year old age group where $67 \%$ of 7172 male deaths and $16.3 \%$ of 938 female deaths were from a communicable disease (mostly AIDS). Similarly, the proportion of deaths due to injury peaked in the 15 to 24 year old age group: $78.4 \%$ of 416 male deaths and $60.4 \%$ of 101 female deaths were caused by an injury. Deaths due to maternal, perinatal, or nutritional causes were $0.6 \%$ of all deaths. Finally, nearly all deaths (99.8\%) were categorized into a cause-of-death evaluated for this study.

[^7]

Figure 4: Standard Expected Years of Life Lost (SEYLL) from the 13 Leading Causes of Death, San Francisco 1990-1995

During the period 1990 through 1995, 48424 San Francisco residents died, resulting in a total of 1.07 million standard expected years of life lost (SEYLL). The 13 overall leading causes of death (Figure 4) includes the ten leading causes for males and females. AIDS was the leading cause of premature mortality overall, followed by ischemic heart disease, lung cancer, stroke, and drug poisoning.

The choice of mortality measures determines the rank order of causes of death. Number of deaths, SEYLL and age-adjusted rates are compared in Table 4. The first three causes for men (AIDS, ischemic heart disease, and lung cancer) and the first two for women (ischemic heart disease and stroke) are the same on all three lists. For both sexes, the leading causes of death ranked by SEYLL and age-adjusted rates share nine out of ten causes, with causes of deaths occurring at younger ages ranking higher on the SEYLL list. For example, among females, AIDS is the tenth leading cause of death ranked by age-adjusted rates, but it is the sixth leading cause of death ranked by SEYLL. Drug poisoning, not ranked in the leading ten causes by age-adjusted rates, displaces chronic liver disease from the top ten when ranked by SEYLL. Among males, ranking by SEYLL resulted in a greater number (four vs. three) and higher ranking of injury causes of death (drug poisoning, suicide, homicide, motor vehicle-traffic) among the ten leading causes. In general, ranking leading causes of death by SEYLL did not change the order for the top three causes for males and the top five for females; however, it resulted in greater weighting of injury causes in males and the inclusion of drug poisoning in the top ten for females.

The Prevention Attribution Matrices (Tables 5-7) show the number of deaths and standard expected years of life lost (SEYLL) for the 20 leading causes of death ranked by SEYLL for all, male, and female residents, respectively. In addition to showing the mortality measures by cause, the right side of each table summarizes the relationship between the leading causes of deaths in San Francisco and nine contributing factors or determinants. These underlying causative factors were identified as being the "actual cause of death" for over half the deaths in the United States in 1990 (see Methods and Reference [35]). With respect to preventable factors, sexual exposure is the leading contributing factor associated with the leading cause of death - AIDS. Of the 13 overall leading causes of death (the top ten for males and females), six were associated with tobacco consumption, nine with alcohol consumption, seven with illicit drug use, and four with diet and physical inactivity (Table 5).

Table 6: Leading Causes of Death and Prevention Attribution Matrix, Males 1990-1995

The Prevention Attribution Matrices qualitatively summarize the contribution of several determinants to each of San Francisco's leading specific causes of death. Likewise, these tables summarize the leading causes of deaths attributable to a single contributing factor. Thus, for example, three of these factors contribute to the City's leading cause of death, AIDS; tobacco contributes to 6 of the 20 leading causes of male deaths, and alcohol contributes to 13 of the 20 leading causes (and is protective for two; Tables 5-7).

### 3.1.2 Racial/ethnic disparity

Although standard expected years of life lost (SEYLL) were used to rank leading causes of death, because of differences in the size and age composition of each demographic group, SEYLL are not an appropriate measure to make comparisons. Therefore, age-adjusted mortality rates were calculated to compare mortality of different race/ethnic groups. The results that follow summarize the mortality burden for San Francisco ethnic groups using mortality rates and rate ratios. In addition, life expectancies at selected ages were calculated and compared. Life expectancy at birth is a intuitive measure of today's total mortality burden and answers the following hypothetical question, "If a person born today were to experience the death rates found in this study, how many years would we expect him or her to live?"

Age-adjusted mortality rates and trends There were marked racial disparities in mortality rates for all causes combined and for specific causes of death. All-cause mortality rate trends for the three consecutive three-year periods between 1987 and 1995 were compared (Figure 5). African-American all-cause mortality rates were, by far, the highest for both sexes. Whites had the next highest mortality rates, with Latinos and Asians/others having the lowest all-cause mortality rates in San Francisco. The trends show a modest mortality rate decline over the period for African American and White males and for females. In spite of the moderate improvements for each group over this nine-year period, the racial/ethnic disparity in mortality rates did not appear to narrow.

Figure 5: San Francisco All-Cause Mortality Rates by Sex and Race/Ethnicity, 1987-1995

Table 8: All-Cause Mortality Rates and Rate Ratios by Sex and Ethnicity

|  | Rate* | 95\% C.I. | Rate Ratios $\dagger$ Total | White | African <br> American | Latino | Asian/ Other |

| Asian/other | 237.8 | (228.8, 246.9) | 0.70 | 0.64 | 0.38 | 1.13 | 1.00 |

*Rate per 100000 per year, age-adjusted to 1940 U.S. standard million population
$\dagger$ Rate ratio $(R R)=($ rate of group from row name $) \div$ (rate of group from column name)
To compare relative differences in mortality rates among males and females, rate ratios for each ethnic group relative to each other and to all groups combined were calculated (Table 8). Non-overlapping $95 \%$ confidence intervals represent mortality rate differences that were statistically significant ( $P$ value $<0.05)$. Rate ratios, shown in the five right-hand columns, are read as the rate for the row group compared to the rate of the column group (serving as the reference group). For example, the second row, last column entry of the table was 2.13 which meant that the mortality rate for all Whites was 2.13 times (or $113 \%$ higher than) the rate of all Asian/others ( $725.6 \div 340.3$ ).

In general, Whites are often chosen as a reference group to make comparisons. However, in Table 8 any group can serve as a reference. For example, African Americans males had the highest all-cause mortality rate, followed by Whites, Latinos, and Asian/others; with the Asian/other mortality rate as a reference (right-hand column), Latino, White, and African American rates were $33 \%$ ( $R R=1.33$ ), $128 \%(R R=2.28)$, and $193 \%(R R=2.93)$ higher, respectively. Among females, African Americans had the highest all-cause mortality rate, followed by Whites, Asian/others, and Latinos; with the Latino mortality rate as a reference, Asian/other, White, and African American rates were $13 \%$ $(R R=1.13), 77 \%(R R=1.77)$, and $199 \%(R R=2.99)$ higher respectively.

For males and females, African American age-adjusted mortality rates were the highest for almost all of the leading causes of death (Figures 6-7). With the exception of AIDS and suicide, AfricanAmerican males had the highest mortality rates among the four ethnic groups for 10 of the 12 leading causes of death in San Francisco. Their mortality rates were significantly higher than the other groups for six of the top eight causes (ischemic heart disease, lung cancer, stroke, drug poisoning, homicide, and pneumonia). With the exception of suicide, chronic obstructive pulmonary disease and motor vehicle-traffic deaths, African American females had the highest mortality rates for 10 of the 13 leading causes of death. Their mortality rates are significantly higher for five of the seven leading causes (AIDS, ischemic hearth disease, stroke, drug poisoning, and homicide) and breast cancer.

See also Section 3.6, p. 74, for ethnicity profiles that summarize leading causes of death for each group.

Life expectancy at selected ages: Although age-adjusted all-cause mortality rates facilitate valid comparisons between different population groups, the actual number is difficult to interpret. For this reason, all-cause mortality rates were used to calculate life expectancy at selected ages for each sex and ethnic group. Recall, life expectancy at birth is a intuitive measure of today's total mortality burden and answers the following hypothetical question, "If a person born today were to experience the death rates found in this study, how many years would we expect him or her to live?" Alternatively, we could ask, "If a 45 years old Latino female were to experience the death rates found in this study, how many years would we expect her to live? The answer, from Table 11, is 44.5 years.

For San Francisco, African Americans had the lowest life expectancy at birth, however the disparity between ethnic groups was greatest among males (Table 11). The life expectancy at birth of 60.0 years for African American males in San Francisco was lower than for other groups and lower than the 1940 U.S. White male life expectancy at birth. The highest life expectancies at birth were for Latino females (87.9 years) and Asian/other females (84.6 years).

Table 11: Life Expectancy at Birth and Selected Ages by Ethnicity and Sex: United States 1940, 1970, 1993; and San Francisco, 1990-1995

| Exact age in years (year) | Males |  |  |  | Females |  |  |  |

*Anderson RN, Kochanek KD, Murphy SL. Report of final mortality statistics, 1995. Monthly vital statistics report; vol 45 no 11, supp 2. Hyattsville, Maryland: National Center for Health Statistics. 1997

Life expectancy in the absence of selected causes of death: If a specific disease or injury could be eliminated as a cause of death, how long would life expectancy at birth be extended? Although hypothetical, the answer to this question highlights those causes of death which, if eliminated, have the greatest potential to improve life expectancy. For the 13 overall leading causes of deaths, Table 12 shows the expected gain in life expectancy at birth that would occur for each sex and race/ethnic group if each cause alone were to be eliminated completely. For example, for White and African American males, the biggest improvement in life expectancy would occur with the elimination of AIDS mortality. In contrast, for all female ethnic groups, especially Latinos, ischemic heart disease has the biggest impact on life expectancy.

Table 12: Improvement in Life Expectancy at Birth (Years) in the Theorectical Absence of Each Leading Cause of Death, by Sex and Ethnicity, San Francisco 1990-1995

| Selected causes of deaths | White | African <br> American | Latino | Asian/ <br> other |
| :--- | :---: | :---: | :---: | :---: |

### 3.1.3 Sex differences

Figure 8: Leading causes of death for males (top) and females (bottom), 1990-1995. For all causes, there were 28,613 male deaths (SEYLL $=776,759$ years) and 19,811 female deaths (SEYLL $=291,450$ years). The 1990 Census population was 723,965 residents.

Among males: AIDS was the leading cause of death, representing $37.7 \%$ of the 776759 expected years of life lost from all causes, followed by ischemic heart disease (11.3\%), and together account for $49 \%$ of years of life lost. The causes of premature deaths were homicide, drug poisoning, AIDS, motor vehicle-traffic, suicide, and cirrhosis, causing an average of $52,45,44,44,40$ and 33 expected years of life lost per death, respectively. Injuries were the fourth, fifth, sixth, and tenth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, stroke, and pneumonia), alcohol with eight (AIDS, drug poisoning, suicide, homicide, stroke, cirrhosis, pneumonia, and MV-traffic), drug use with seven (AIDS, drug poisoning, suicide, homicide, stroke, cirrhosis, MV-traffic) and diet/physical inactivity with three (ischemic heart disease, lung cancer, stroke) (Table 6, p. 24).

Among females: Ischemic heart disease was the leading cause of death, representing $18.3 \%$ of the 291450 expected years of life lost from all causes, followed by stroke ( $7.3 \%$ ), and lung cancer (5.9\%). The causes of premature deaths were AIDS, drug poisoning, and suicide, causing an average of 45,43 and 34 expected years of life lost per death, respectively. Injuries were the sixth and tenth leading causes of death. Tobacco was associated with seven leading causes (ischemic heart disease, stroke, lung cancer, breast cancer, pneumonia, colorectal cancer, and chronic obstructive pulmonary disease), alcohol with six (stroke, breast cancer, pneumonia, AIDS, colorectal cancer, suicide, and drug poisoning), drug use with four (stroke, AIDS, suicide, drug poisoning) and diet/physical inactivity with five (ischemic heart disease, stroke, lung cancer, breast cancer, colorectal cancer) (Table 7, p. 25).

### 3.1.4 Age differences

Table 3, presented earlier, summarized the distribution of deaths by age group, sex and major cause of death category (communicable, maternal-perinatal-nutritional, noncommunicable, injury). This section presents the leading specific causes of death by age group and sex. Tables 13-15 show the leading causes of death by age group: for the whole population (Table 13), for males (Table 14), and for females (Table 15).

From 1990 through 1995, the following results are summarized from Table 13:

- 362 infants less than one year old died (average of 60 per year), representing 29865 expected years of life lost. Sudden Infant Death Syndrome (SIDS) was the leading cause of infant death: 85 deaths and 7012 expected years of life lost. SIDS was followed by congenital anomalies (70 deaths, 5775 expected years of life lost), and birth asphyxia \& trauma ( 43 deaths, 1155 expected years of life lost). Four infants died from homicide and three died from AIDS.
- 72 infants/toddlers, ages one to four, died (average of 12 per year), representing 5892 expected years of life lost. In this age group congenital anomalies was the leading cause of death (16 deaths, 1309 expected years of life lost), followed by homicide ( 7 deaths, 573 expected years of life lost), motor vehicle-traffic accidents (5 deaths, 409 expected years of life lost), and fires (4 deaths, 327 expected years of life lost).
- 76 children, ages 5 to 14 years, died (average of 13 per year), representing 5726 expected years of life lost. In this age group motor vehicle-traffic accidents were the leading cause of death (15 deaths, 1130 expected years of life lost), followed by congenital anomalies ( 8 deaths, 594 expected years of life lost), homicide ( 7 deaths, 521 expected years of life lost), and leukemia (5 deaths, 385 expected years of life lost).
- 517 young adults, ages 15 to 24 years, died (average of 86 per year), representing 33329 expected years of life lost. In this age group homicide was the leading cause of death ( 157 deaths, 10180 expected years of life lost), followed by suicide ( 79 deaths, 5067 expected years of life lost), motor vehicle-traffic accidents ( 78 deaths, 5024 expected years of life lost), AIDS ( 30 deaths, 1892 expected years of life lost), and drug poisoning ( 22 deaths, 1398 expected years of life lost).
- 8110 adults, ages 25 to 44 years, died (average of 1352 per year), representing 394595 expected years of life lost. In this age group AIDS was the leading cause of death ( 4640 deaths, 224627 expected years of life lost), followed by drug poisoning ( 506 deaths, 25035 expected years of life lost), suicide ( 350 deaths, 17534 expected years of life lost), homicide ( 264 deaths, 13821 expected years of life lost), and chronic liver disease ( 189 deaths, 8952 expected years of life lost).
- 8845 adults, ages 45 to 64 years, died (average of 1474 per year), representing 279156 expected years of life lost. In this age group AIDS was the leading cause of death ( 2031 deaths, 71666 expected years of life lost), followed by chronic conditions for which mortality increases greatly with aging: ischemic heart disease, lung cancer, chronic liver disease, and stroke.
- 30339 older adults, aged 65 years or older, died (average of 5057 per year), representing 319646 expected years of life lost. The leading cause of death was ischemic heart disease, followed by stroke, lung cancer, pneumonia, and COPD.

Homicide was between the first and seventh leading cause of death in each age group from birth through 44 years. AIDS was between the first and eighth leading cause of death in every age group from birth through 64 years. Motor vehicle-traffic accidents were between the first and sixth leading cause of death in every age group from 1 through 44 years.

Breast cancer was between the second and sixth leading cause of death for females in all age groups from 25 years or older (Table 15, p. 36). In contrast, prostate cancer, an exclusively male cancer, was as high as the sixth leading cause of death only for males 65 years or older (Table 14, p. 35).

### 3.1.5 Comments

The cause of death categories in this report are more specific than those used by the National Center for Health Statistics. This was done partly to follow the categories used in the WHO Global Burden of Disease and Injury Report, and partly because more specific causes of death are more useful for planning prevention actions. We report on cancers of specific sites rather than all cancers, and unintentional injuries of particular types rather than all unintentional injuries, so that the Department and the public can better target which types of cancers or injuries pose a greater burden of premature mortality, and which interventions might best reduce this burden.

We used the international classification of disease (ICD-9) categories for the "underlying cause of death" listed on the death certificates to develop a systematic and comprehensive analysis of all deaths from all underlying causes. Mortality data from all causes provided in the Appendix. Here, we present data for and discuss only the leading causes of deaths. This allows users of this report to focus on the diseases causing the greatest burden of premature death, for San Francisco as a whole and for each of its many communities.

Comparisons within groups: Many of the leading causes of death are shared across population groups. A few can be identified as more important in particular groups or areas.

Rankings within groups describe the relative importance of causes of death in a group, but they do not quantify the relative importance of causes. For that, it is useful to look at the proportion of a group's total SEYLL represented by the various leading causes. For each group, all but a handful of causes contribute less than $5 \%$ to the total mortality of that group. This partly reflects the skewing effects of AIDS, which represents such a large part of SEYLL among White, African American and Latino men, and consequently leaves a smaller percentage for all the rest of the causes. Among females AIDS does not exert this effect on mortality proportions, but still there are no more than four causes contributing more than $5 \%$ of any female group's total SEYLL. Only ischemic heart disease causes more than $10 \%$ of total SEYLL among all ethnicities, and stroke is a similarly cause of death among Asian females.

Comparisons of rankings across ethnic groups or geographic areas can be used to show differences in the relative importance of particular causes or clusters of causes across those groups. But we cannot directly compare numbers of SEYLL across groups that have different size populations or age distributions, as all ethnic groups and ZIP code based areas do. Such comparisons are best based on the rate of mortality per cause per unit of population in each group. Age-adjusted rates in particular, while not very meaningful in themselves, have been developed for the purpose of comparing across groups of different sizes and mixes of ages. (They are calculated by applying the age-specific rates of each group to the same standard population and adding the results.) Thus for example, stroke ranks lower among causes of death among African American males (sixth) than it does among Asian males (fourth) or, even though the rate of stroke is $64 \%$ higher among African American males (55.7) than it is among Asian males (33.9). (see Tables 22 and 23, pp. 46-47).

Comparisons across groups: Tables 9 and 10 (pp. 28-29) show mortality rates by race/ethnicity for the leading causes of death. On the same pages, Figures 6 and 7 display these rates graphically. Non-overlapping $95 \%$ confidence interval represent significant differences in rates.

African American males and females stand out as having the highest rates for most of the leading causes. Their rates are significantly higher than any other group for all-cause mortality and for 6 of the 12 leading specific causes of death among males, and 7 of the 13 leading causes among females. The only other group with significantly higher rates are White males, for AIDS and suicide. Asian males and females have the lowest rates for the causes that are most clearly drug and alcohol-related (drug poisoning and chronic liver disease). Also, Asians have the lowest overall mortality rates among males and for AIDS. Latinos have the lowest mortality rates for the two causes of death that are most strongly tobacco-attributable, lung cancer and COPD (though the COPD rate for Latino females is not significantly lower than for Asian females). Latino females have the lowest death rate overall and for suicide.

Male death rates are significantly higher than female death rates for all the leading causes, except breast cancer. African American and White males have all the significantly high rates, and Latino
and Asian females have significantly lower rates, overall and for each of the leading causes of death.

Comparisons across time: The time trends shown in Figures 5, 9 and 11 through 22, compare recent changes in death rates, over the periods 1987-1989, 1990-1992, and 1993-1995, for overall mortality and for each of the leading causes of death. They show that rates for many causes and many sex-ethnicity groups appear to have stayed steady or declined somewhat.

Healthy People 2000 objectives The Healthy People 2000 objectives were established to allow federal, state and local health jurisdictions to work toward commonly agreed on health targets during this decade. San Francisco's progress toward these national targets is shown in the right-hand columns of Tables 9 and 10 (pp. 28-29). Most of the Healthy People 2000 objectives represent a single target for the whole population. These Tables allow comparisons of this single target to each sex-and-ethnicity group with data for San Francisco, to show how each part of the population is doing in relation to the national standard. In some cases HP2000 sets different objectives for some subgroups with higher rates; however, in keeping with our approach of adopting a single standard for the whole population - an approach that will be recognized as a national goal in Healthy People 2010 - we present only the objective set for the whole population.

Not all the leading causes of premature mortality have corresponding Healthy People 2000 objectives, and some have related objections that don't allow direct comparisons. Some of the HP2000 standards use crude rates, that is, rates per 100,000 people, regardless of age distribution. Since rates for virtually all causes vary by age group, such crude rates do not provide a good basis for inter-group comparisons. This is especially true for San Francisco, which has both an older population than the state or nation, and large ethnic group populations with very different age distributions and mortality rates. Age-adjusted rates which allow for comparisons across such groups, are therefore the only HP2000 objectives presented.

Factors contributing to the leading causes of death: Knowledge of the leading causes of premature deaths is not, by itself, sufficient to prevent the occurrence of disease and injury. Nevertheless, if we are to design cost-effective strategies to prevent or control disease and injury, we must first measure and rank the leading causes of disease and injury, identify the underlying determinants of these causes of disease and injury (Tables 5-7, pp. 23-25), calculate the contribution of these determinants to the leading causes of death, and finally assess the distribution of these determinants in our population. With these facts, the health model shown in Figure 3 (p. 12) can be used to guide, plan, and monitor improvements in population health, making the best use of this disease and injury mortality data. Disease and injury are shown in the middle of the diagram, along with health and medical care; well-being and prosperity are shown at the bottom, and environmental influences at the top. The more we can understand how the middle and bottom sections of the model are influenced by the factors at the middle and top of the model, the better we will be able to develop policies that protect, preserve, and promote population health and well-being.

The model in Figure 3 shows that exposures to many determinants of disease and injury are influenced by the social environment. Changes in social conditions may have many beneficial effects on community health. For example, laws to reduce exposures to second-hand tobacco smoke, to limit cigarette advertising, or to permit the provision of clean needles and syringes to injection drug users, not only saves lives, they improve health and quality of life. Further, social conditions affect individuals' access to educational, social, and health resources. Increasing access to such resources could provide substantial benefits to the health of many individuals, especially to those who have the least access due to socioeconomic disadvantage.

Indeed, socioeconomic conditions, especially poverty, adversely influence many health outcomes, including almost all of the leading causes of death. Other aspects of the social environment also have wide-ranging influences on many health outcomes, such as the availability of social support. Furthermore, individuals who experience substantial stress in their social environment are also at increased risk of poor health. Thus, improving these social conditions, especially for the most vulnerable segment of the population, could be expected to provide the most widespread improvement in health and
well-being. Thus, efforts to improve community health should not to be limited to clinical or behavioral interventions, but should also aim for long-term change in the social and physical environments in which we live. We hope that the results presented in this report will help diverse communities, separately and together, to set priorities and advocate for changes that improve their health.

This report links causes of death responsible for the greatest burden of premature mortality in San Francisco to nine well-established determinants that contribute to mortality from multiple specific causes of death. The prevention attribution matrices (Tables 5-7, pp. 23-25) are our evidenced-based attempt to make these critical linkages, to guide new prevention efforts, and to target monitoring of expected outcomes. The prevention attribution matrix for the City's overall leading causes of premature mortality can indicate the extent to which prevention efforts directed at reducing exposure to the determinants covered in this report could affect the burden of mortality from the leading causes for the City as a whole or for communities where prevention might be targeted. Primary prevention strategies-aimed at preventing the occurrence of disease or injury in the first place - that accomplish long-lasting change in the distribution of risk factors (e.g., smoking prevalence) can continue to improve population health generations into the future. The analysis provided by this report helps provide a basis to effectively protect, preserve, and promote community health-to invest in targeted strategies that improve population health today and into the future.

### 3.2 Burden of AIDS deaths

For the period 1990 through 1995, 6832 San Francisco residents died from AIDS, representing 300755 standard expected years of life lost (Table 16). Male deaths from AIDS numbered 6650 and represented 292636 standard expected years of life lost; this was more than all the expected years of life lost for females from all causes. Female deaths from AIDS numbered 182 and represented 8119 standard expected years of life lost (Table 16).

For males, AIDS was the first leading cause of death overall, and the first leading cause of death for ages 25-44 and ages 45-64. AIDS was the first leading cause of death for White, African American, Latino, and Native American males, and the second leading cause of death for Filipino males. For females, AIDS was the sixth leading cause of death overall, and the first leading cause of death for the ages 25-44. AIDS was the second leading cause of death for African American and Latino females.

In every San Francisco neighborhood, AIDS was the first or second leading cause of male deaths (Table 18). For females, AIDS was the second leading cause of death in ZIP code 94102 (Hayes Valley Tenderloin - North of Market), and the fourth leading cause of death in the ZIP codes 94115 (Western Addition - Japantown), 94124 (Bayview - Hunters Point), and 94134 (Visitación Valley - Sunnyvale).

The trends in AIDS mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 9. For males, Whites had the highest mortality rates that peaked during the 19901992 period and have declined since. African American males had the second highest mortality rates which climbed during this period and, for the final period 1993-1995, the rate was not statistically different compared to the rate for Whites. Latino males had the third highest AIDS mortality rates which, similar to Whites, peaked in the 1990-1992 period. Asian/other males had the lowest AIDS mortality rates, but the rates continually increased over the period. For females, African Americans had the highest AIDS mortality rates and were the only female ethnic group with a significant increasing trend during this period. Age-adjusted AIDS mortality rates by sex and ethnicity for the combined period 1990 through 1995 are shown in Table 17.

Table 16: Burden of AIDS Deaths by Age and Sex, and by Ethnicity and Sex, 1990-1995

In every San Francisco neighborhood, AIDS was the first or second leading cause of male deaths (Table 18).

### 3.2.1 Comments

San Francisco was one of the cities most seriously affected by the AIDS epidemic that developed throughout the 1980s. In the gay male community, infection levels were estimated to have reached over $45 \%$ in 1984 [58]. By 1995, it is estimated that over 20000 members of the City's estimated 58000 gay males had been diagnosed with AIDS [27]. However, San Francisco became a national leader in its response - in terms of surveillance, support and prevention services, as well as the provision of care.

This report, covering 1990 through 1995, spans the time at which AIDS diagnoses and deaths were at their highest levels, both the number of AIDS cases diagnosed and the number of AIDS deaths peaked in 1992 (at 3093 cases diagnosed and 1816 deaths) [48]. The incidence of both AIDS diagnoses and deaths has been declining since 1995 [48], and it is believed that the incidence of new AIDS cases and HIV infections may be leveling off [30, 25]. Because of improvements in treatment and care services, longevity with the HIV infection at all stages has improved, and the number of people living with HIV and AIDS in San Francisco has been increasing [48]. While in the coming years, AIDS may be expected to remain a significant cause of morbidity and premature death, it is likely that it will be less prominent than during the period 1990-1995.

### 3.3 Burden of tobacco consumption

Tobacco has played an important role in our national history, but an impressive body of scientific evidence shows that nicotine is addictive and lethal. Tobacco's role as a contributor to the leading causes of death is depicted in Tables 5-7. As can be seen in Table 19, tobacco contributes to premature death from an even wider array of diseases. This table, which links tobacco use to specific causes of death, is based on tobacco-attributable mortality for California as a whole [44]. These tobacco-related mortality attributions, which were applied to San Francisco mortality, 1990 through 1995, are similar to the mortality attributions obtained from national reports. Approximately $14 \%$ of deaths and $10 \%$ of SEYLL can be attributed to tobacco.

The pages that follow present an analysis of deaths from lung cancer, stroke, chronic obstructive pulmonary disease (COPD), and pneumonia. There are other risk factors for each of these diseases, especially for pneumonia, but tobacco is a major contributor to these four leading causes of premature death in San Francisco. Although ischemic heart disease is also an important consequence of tobacco use, it is reported elsewhere (Section 3.5, p. 3.5), a reflection not that tobacco is not an important contributor to this cause (it is), but of our hope that prevention activities as robust as those directed at tobacco use will become manifest for diet and physical inactivity.

Table 19: Number of Deaths and Expected Years of Life Lost Attributed to Tobacco Consumption by Cause, 1990-1995

|  | Total |  | Tobacco |  |  |

SEYLL $=$ Standard Expected Years of Life Lost, AF $=$ Attributable Fraction

### 3.3.1 Lung Cancer Deaths

For the six-year period 1990 through 1995, 2455 San Francisco residents died from lung cancer, an average of 409 deaths per year, and representing 45351 standard expected years of life lost (Table 20).
There 1439 male deaths, representing 28046 standard expected years of life lost, and 1016 female deaths, representing 17305 standard expected years of life lost. Average years of life lost per death was 19 years for males and 17 years for females, indicating that death from lung cancer occurs at relatively older ages.

For males, lung cancer was the third leading cause of death overall and for ages 45 to 64 years, and the second leading cause of death for ages 65 years or older. It was the second leading cause of death for Asian males, fourth for Filipinos, and fifth for Whites and African Americans. For females, lung cancer was the third leading cause of death overall and for the ages groups 45 to 64 years and 65 years or older. Lung cancer was the second leading cause of death for White females, third among Asians, and fourth among African Americans.

Lung cancer was the third or fourth leading cause of male deaths in 16 of 22 neighborhoods (Table 47, p. 83). For females, lung cancer was the second leading cause of death in ZIP codes 94114 (Castro, Noe Valley), 94127 (St. Francis Wood, Miraloma / Seaside), and 94131 (Twin Peaks-Glen Park); it was ranked lower than 5th in only two ZIP codes (Table 48, p. 84).

The trends in lung cancer mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 10. For males, African Americans had the highest mortality rates, followed by Whites, Asians, and Latinos with the lowest rates. Rates declined (not significantly) among all male ethnic groups during the periods studied, with larger declines in the groups with higher rates. For females, African Americans had the highest lung cancer mortality rates, followed by Whites. These varied slightly over time. Latinos started with the lowest lung cancer mortality rates, significantly below Asian/Pacific Islanders, but these two groups' rates converged over the periods studied. No group showed a significant change in mortality.

| African American | 82.2 | (71.3, 93.1) | 1.64 | 36.0 | (29.3, 42.7) | 1.18 |
| Latino | 15.8 | (11.3, 20.4) | 0.32 | 6.9 | $(4.4,9.5)$ | 0.23 |
| Asian/other | 34.8 | $(31.0,38.7)$ | 0.70 | 13.1 | (11.0, 15.2) | 0.43 |

### 3.3.2 Stroke Deaths

For the period 1990 through 1995, 3374 San Francisco residents died from stroke, an average of 562 a year, and representing 41182 standard expected years of life lost (Table 22). There were 1345 male deaths, representing 19838 standard years of life lost, and 2029 female deaths, representing 21343 standard years of life lost. Average years of life lost per death was 15 years for males and 11 for females, indicating that death from stroke occurs at relatively older ages.

For males, stroke was the seventh leading cause of death overall, and the third leading cause of death for ages 65 or older. Stroke was the third leading cause of death for Filipino males, and the fourth leading cause of death for Asian males. For females, stroke was the second leading cause of death overall, and the second leading cause of death for ages 65 or older. Stroke was the second leading cause of death for Asian and Filipino females, and third for Whites, African Americans and Latinos.

Stroke was the fourth leading cause of male deaths in nine ZIP codes (Table 47, p. 83): 94116 (Parkside), 94118 (Inner Richmond), 94121 (Outer Richmond), 94122 (Sunset), 94123 (Marina), 94127 (St. Francis Wood, Miraloma / Seaside), 94132 (Lake Merced), 94133 (North Beach / Chinatown), and 94134 (Visitación Valley / Sunnydale). It was as low as the 11th leading cause, in three ZIP codes. Stroke was the second or third leading cause of female deaths in all but three San Francisco neighborhoods, and no lower than sixth in any (Table 48, p. 84).

The trends in stroke mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 11. For males, African Americans had significantly higher stroke rates throughout the periods studied. Rates for all ethnic groups declined slightly (but not significantly) between the 1990-1992 and 1993-1995 periods. For females, African Americans had significantly higher stroke rates throughout the periods studied, and Latinos the lowest. Rates for all groups declined slightly (not significantly) between the 1987-1990 and 1990-1992 periods.

### 3.3.3 COPD Deaths

For the period 1990 through 1995, 1391 San Francisco residents died from chronic obstructive pulmonary disease (COPD), an average of 232 deaths per year and representing a total of 18894 standard expected years of life lost (Table 24). There were 769 male deaths, representing 11072 standard expected years of life lost, and 622 female deaths, representing 7823 standard expected years of life lost. Average years of life lost per death was 14 years for males and 13 years for females, indicating that most deaths from COPD occurs at older ages.

COPD was the fifth leading cause for ages 65 or older (overall and for both sexes). For males, COPD was the eleventh leading cause of death overall, and COPD was the eighth leading cause of death for Asian males, and the ninth for Filipino males. For females, COPD was the eighth leading cause of death overall. COPD was the sixth leading cause of death for White females.

COPD was the fifth leading cause of male deaths in ZIP code 94133 (North Beach / Chinatown), and the sixth leading cause of male deaths in ZIP codes 94108 (Chinatown) and 94118 (Inner Richmond), and it was among the top ten causes in three others (Table 47, p. 83). For females, COPD was the fifth leading cause of death in ZIP code 94122 (Sunset), and the sixth leading cause of female deaths in ZIP codes 94115 (Western Addition / Japantown), 94116 (Parkside), 94117 (Haight-Ashbury), 94121 (Outer Richmond), 94123 (Marina), and 94131 (Twin Peaks-Glen Park) (Table 48, p. 84).

The trends in COPD mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 12. For males, African Americans and Whites had the highest COPD mortality rates, but the rate for all ethnicities declined (none significantly) from 1990-1992 through 1993-1995. Rates for Whites and African Americans also declined from the previous period (1987-1989). For females, Whites had the highest COPD mortality rates, and Latino females had the lowest rates, throughout. There were no noticeable trends evident over the time period.

### 3.3.4 Pneumonia Deaths

For the period 1990 through 1995, 2303 San Francisco residents died from pneumonia, an average of 384 per year and representing 27634 standard expected years of life lost (Table 26). There were 1109 male deaths, representing 17127 standard expected years of life lost, and 1194 female deaths, representing 10507 standard expected years of life lost. Average years of life lost per death was 15 years for males and 9 years for females, indicating that most pneumonia deaths occurred at older ages. It was the fourth leading cause of death for ages 65 years or older, overall and for both sexes.

For males, pneumonia was the ninth leading cause of death. It was the seventh leading cause of death for White and African American males, and the eighth leading cause of death for Filipino males. For females, pneumonia was the fifth leading cause of death overall. Among White, Asian/other, and Filipino females it was the fifth leading cause of death.

Pneumonia was the fifth leading cause of male deaths in ZIP code 94131 (Twin Peaks-Glenn Park), and the sixth leading cause of male deaths in ZIP codes 94109 (Polk / Russian Hill), 94121 (Outer Richmond), 94123 (Marina), 94132 (Lake Merced), and 94133 (North Beach / Chinatown); it was in the top ten in all but two neighborhoods (Table 47, p. 83). For females, pneumonia was the fourth leading cause of death in ZIP code 94108 (Chinatown), and the fifth leading cause of death in ZIP codes 94109 (Polk / Russian Hill), 94112 (Ingleside-Excelsior / Crocker-Amazon), 94114 (Castro, Noe Valley), 94115 (Western Addition / Japantown), 94116 (Parkside), 94118 (Inner Richmond), 94123 (Marina), 94127 (St. Francis Wood, Miraloma / Seaside), and 94133 (North Beach / Chinatown); it was in the top ten in all but two neighborhoods (Table 48, p. 84).

The trends in pneumonia mortality rates for the period 1987 through 1995 are displayed in Figure 13. For males, African Americans and Whites had the highest mortality rates during the 1987-1989 period, but the rates for African American males climbed, becoming significantly greater than Asians and Latinos during subsequent periods. For females, African Americans had the highest pneumonia mortality rates during all of the period studied, significantly higher than the other ethnic groups in 1987-1989 but not in either period since.

### 3.3.5 Comments for Tobacco

Tobacco is the leading preventable cause of death in the United States, accounting for an estimated 400,000 deaths per year [35]. Smoking is associated with many of the leading causes of death in San Francisco, as shown in Table 19. Most smoking-related deaths occur after many years of exposure, but recent research has shown that smoking during pregnancy is an important risk for sudden infant death syndrome [2]. The increase in smoking among women during recent decades is now becoming evident in mortality data. In 1986, lung cancer surpassed breast cancer as the leading cause of cancer death among women in the United States [16]; this trend is also apparent in San Francisco.

Not depicted in Table 19 is the way in which smoking interacts with common diseases, such as diabetes and hypertension, to greatly increase their risk of fatal outcomes, nor does it show how smoking can contribute to high cholesterol. Diabetes, hypertension, and high cholesterol are major risks for ischemic heart disease and stroke, which are leading causes of death in San Francisco.

More than $80 \%$ of lung cancer deaths can be attributed to tobacco. By studying the relative importance of lung cancer deaths among the various the various ethnic groups and neighborhoods of San Francisco, one can gain a rough idea of how the burden of smoking is felt in various segments of the population of the City. In some cases, studies in the medical literature support these associations. For example, a survey of Latino women in San Francisco [41] found that they smoke far less than their White counterparts, which may explain their lower lung cancer mortality rates.

### 3.4 Burden of alcohol and illicit drug consumption

Alcohol and illicit drugs contribute to many causes of premature death. The specific causes that are grouped in this section (Drug Poisoning, Suicide, Homicide, Chronic Liver Disease, and Motor Vehicle-Traffic) are the leading causes of premature death in San Francisco for which a significant portion can be attributed to alcohol and illicit drugs. There are, of course, other risks for these causes of premature death, and there are other causes of premature death attributable to alcohol and illicit drugs (see Tables 5-7). Nevertheless, the grouping of these leading causes of death in this single section underscores the potential benefits of prevention efforts directed at reducing the burden of premature mortality attributable to alcohol and illicit drugs.

Table 28 applies alcohol-attributable mortality fractions that were previously calculated for California as a whole [42] to deaths and SEYLL for San Francisco for 1990 through 1995. These attributable mortality fractions are similar to those that have been reported nationally [12]. This table illustrates the large burden of alcohol-attributable mortality that can be assigned to the leading causes of death that are analyzed on the pages that follow, as well as to other causes of death.

Table 28: Number of Deaths and Expected Years of Life Lost Attributed to Alcohol Consumption by Cause, 1990-1995

|  | Total |  | Alcohol |  |  |

### 3.4.1 Drug Poisoning Deaths

For the period 1990 through 1995, 735 San Francisco residents died from unintentional drug poisoning (primarily from illicit drug overdose), an average of 123 deaths per year, and representing 33023 standard expected years of life lost (Table 29). There were 588 male deaths, representing 26636 standard expected years of life lost, and 147 female deaths representing 6387 standard expected years of life lost. Average years of life lost per death was 45 years for males and 43 years for females, indicating that death from drug poisoning occurred at relatively younger ages.

For males, unintentional drug poisoning was the fourth leading cause of premature mortality overall, and the second leading cause for ages 25 to 44 . It was the third leading cause for Native Americans (six deaths), and the fourth leading cause of White, African American, and Latino mortality. For females, unintentional drug poisoning was the tenth leading cause of mortality overall, and the second leading cause for ages 25 to 44 . It was the sixth leading cause for African Americans, and ninth for Whites.

Unintentional drug poisoning was the third leading cause of male deaths in ZIP codes 94102 (Hayes Valley / Tenderloin / N. of Market), 94103 (South of Market), and 94107 (Potrero Hill), and the fourth leading cause of male deaths in ZIP codes 94110 (Inner Mission / Bernal Heights) and 94117 (HaightAshbury); it was among the top ten causes in 16 neighborhoods (Table 47, p. 83). For females, unintentional drug poisoning was second leading cause of death in ZIP codes 94103 (South of Market) and 94107 (Potrero Hill), and the third leading cause of death in ZIP code 94102 (Hayes Valley / Tenderloin / N. of Market); it was in the top ten causes in eight neighborhoods, but in another six, was not even in the top 20 (Table 48, p. 48).

The trends in unintentional drug poisoning mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 14. For males, African Americans had the highest mortality rates. White and Latino males had the second highest mortality rates; the White rate climbed significantly, while that of Latino males declined slightly. Asian/other males had the lowest rates. For females, African Americans had the highest unintentional drug poisoning mortality rates, Whites had the second highest rates, and Latino and Asian/other rates were the lowest.

### 3.4.2 Suicide Deaths

For the period 1990 through 1995, 845 San Francisco residents died from suicide, an average of 141 per year, and representing 32729 standard expected years of life lost (Table 31). There were 645 male deaths, representing 25922 standard expected years of life lost, and 200 female deaths representing 6807 standard expected years of life lost. Average years of life lost per death was 40 for males and 34 for females, indicating that death from suicide occurred at relatively younger ages.

For males, suicide was the fifth leading cause of death overall, second for ages 15 to 24 , and third for ages 25 to 44 . It was the third leading cause for White males, and sixth and seventh for Latinos and Asian/Pacific Islanders (non-Filipino), respectively. For females, suicide was the ninth leading cause of death overall, and the seventh leading cause of death for White and Asian/other.

Among males, suicide was the third leading cause of death in ZIP codes 94108 (Chinatown), 94109 (Polk / Russian Hill), 94114 (Castro, Noe Valley), 94117 (Haight-Ashbury), and 94131 (Twin PeaksGlen Park); it was among the nine leading causes in all but one neighborhood (where it was 11th). (Table 47, p. 83). For females, suicide was the third leading cause death in ZIP codes 94104, 94105, 94111 (which encompass the Rincon / Telegraph Hill / Embarcadero neighborhoods), and was among the ten leading causes of death in more than half of all San Francisco neighborhoods (Table 48, p. 84).

The trends in suicide mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 15. For males, Whites had significantly higher mortality rates, which increased slightly over the period. African American males had the second highest rates, which also slightly increased. Asians, with the lowest rates, and Latinos showed little variation over time. Among females, Whites had the highest rates, which declined slightly to the a level where they were not significantly higher in period 1993-1995 than African American and Asian females.

### 3.4.3 Homicide Deaths

For the period 1990 through 1995, 557 San Francisco residents died from homicide, an average of 93 per year, and representing 28571 standard expected years of life lost (Table 33). There were 456 male deaths, representing 23913 standard expected years of life lost, and 101 female deaths representing 4658 standard expected years of life lost. Average years of life lost per death was 52 for males and 46 for females, indicating that death from homicide occurred at younger ages.

For males, homicide was the seventh leading cause of death overall; it was the first leading cause of death for ages 15 to 24 ( 143 deaths), and the fourth leading cause for ages 25 to 44 ( 213 deaths). It was the second and third leading cause for Latino and African American males, respectively. For females, homicide was the sixth leading cause of death overall; it was the third leading cause of death for ages 15 to 24 ( 14 deaths), and the fifth leading cause for ages 25 to 44 ( 51 deaths). It was the seventh and ninth leading cause for African American and Latino females, respectively, and it was not among the top 20 in the other groups.

Among males, homicide was among the ten leading causes of deaths in 15 out of 22 San Francisco neighborhoods. Homicide was the leading cause of premature male deaths in ZIP code 94124 (BayviewHunters Point), the third leading cause in ZIP codes 94110 (Inner Mission / Bernal Heights), 94112 (Ingleside- Excelsior / Crocker-Amazon), and 94134 (Visitación Valley / Sunnydale), and the fourth or fifth leading cause in four other neighborhoods (Table 47, p. 83). Among females, homicide was among the ten leading causes of deaths in 5 out of 22 neighborhoods. It was the fifth leading cause in ZIP code 94103 (South of Market), and the sixth leading cause of female deaths in ZIP code 94124 (Bayview-Hunters Point) (Table 48, p. 84).

The trends in homicide mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 16. For males, African Americans had the highest rates - about ten times higher than Whites - which increased over the time period. Latino males had the second highest rates. For females, African Americans had the highest homicide mortality rates - about seven times higher than Whites - which did not change significantly over time. The rates remained flat and low over this time period for the other female ethnic groups.

### 3.4.4 Chronic liver disease

For the period 1990 through 1995, 771 San Francisco residents died from chronic liver disease, an average of 129 per year, and representing 23871 standard expected years of life lost (Table 36). There were 551 male deaths, representing 18018 standard expected years of life lost, and 220 female deaths, representing 5854 standard expected years of life lost. Average years of life lost per death was 33 for males and 27 for females, indicating that death from cirrhosis occurred at relatively younger ages.

Chronic liver disease ranked as the ninth leading cause of death overall, eighth among males, and eleventh among females. It ranked between fourth and sixth leading cause for ages 25 to 64 in for both sexes. For males, it was the fifth leading cause of death for Latinos, sixth for Whites, and second for Native Americans (13 deaths). For females, was the eleventh leading cause of death overall, the fifth for Latinos, and the leading cause for Native Americans (5 deaths).

In 17 out of 22 San Francisco neighborhoods, chronic liver disease was among the ten leading causes of male deaths. It was the fourth leading cause of male deaths in ZIP code 94102 (Hayes Valley / Tenderloin / N. of Market) (Table 47, p. 83). For females, chronic liver disease was among the ten leading causes of death in 5 out of 22 San Francisco neighborhoods, including being the fourth leading cause of death in ZIP code 94103 (South of Market) (Table 48, p. 84).

The trends in chronic liver disease mortality by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 18. African American, White, and Latino males had the highest chronic liver disease mortality rates, which have continued to overlap while they declined steadily over the time periods reported. Asian males have maintained significantly lower mortality rates. For females, African Americans had the highest chronic liver disease mortality rates, followed by Whites and Latinos, but these rates have declined (significantly so for African Americans) and converged in the latest time period (1993-1995).

### 3.4.5 Motor Vehicle-Traffic Deaths

For the period 1990 through 1995, 438 San Francisco residents died from motor vehicle traffic injuries, an average of 73 per year, and representing 18444 standard expected years of life lost. There were 296 male deaths, representing 13149 standard expected years of life lost, and 142 female deaths representing 5294 standard expected years of life lost (Table 37). Average years of life lost per death was 44 for males and 37 for females, indicating that death from traffic injuries occurred at relatively younger ages.

Motor vehicle-traffic injuries were the leading causes of death among ages 5 to 14, or between among the top three leading causes of death for ages 1 to 24 . For males, motor vehicle traffic injuries were the fifth, seventh and eighth leading causes of premature mortality for Filipino, Latino, and African American males, respectively. For females, motor vehicle-traffic injuries were the 12th leading cause of death overall, and they were the eighth leading cause of death for Asian females.

For males, motor vehicle-traffic injuries were among the ten leading causes of deaths in nine ZIP codes, including being the fifth leading cause of death in ZIP codes 94112 (Ingleside-Excelsior / Crocker Amazon), 95122 (Sunset), and 94134 (Visitación Valley / Sunnydale) (Table 47, p. 83). For females, motor vehicle traffic injuries were among the ten leading causes of death in nine neighborhoods, including being the sixth leading cause of death in ZIP code 94118 (Inner Richmond), and the seventh leading cause of death in ZIP codes 94123 (Marina) and 94134 (Visitación Valley / Sunnydale) (Table 48, p. 84).

The trends in motor vehicle traffic-injury mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 18. For males, African Americans in 1987-1989 had higher rates than the other three groups. Since then, the rates have converged somewhat.

### 3.4.6 Comments for Alcohol

Alcohol contributes to premature mortality by increasing the risk of injury, by increasing the risk of some types of cancer, by its toxic effects on the liver when large amounts are drunk on a regular basis, and by other means, such as potentiating the effects of other drugs. The greatest risks associated with alcohol occur with heavy drinking, whether acutely or chronically. However, even modest consumption increases the risk of injuries.

The high rate of breast cancer in the San Francisco Bay Area has been attributed, in part, to the high rates of alcohol consumption in the region [45]. There are other preventable risks for breast cancer, such as physical inactivity $[10,18,36]$ and overweight $[4,36]$, but there is now compelling evidence that women who regularly consume two or more drinks per day are at increased risk for breast cancer $[36,50,57]$.

The causes of homicide are complex, but there is evidence that the high rates of assaultive violence that occur in some neighborhoods can be associated with the high concentration of alcohol outlets in those neighborhoods [46]. This finding merits further study in San Francisco, which has the highest concentration of alcohol outlets in California.

No discussion of the potentially harmful effects of alcohol can ignore its considerable beneficial effect in reducing ischemic heart disease mortality [7]. For many individuals, this beneficial effect of moderate drinking outweighs the risks associated with alcohol. However, there are arguments against a general recommendation to "drink for health." First, considering the well-established risks for heart disease, it would seem that the avoidance of smoking, adoption of a healthier diet, and increases in physical activity would be a safer approach, and this approach would also decrease the risk of many other causes of mortality. A second perspective is to weigh the risks and benefits for various age groups [37]. For those younger than 30, alcohol's main effect is to increase the risk of injury morality; this age group does not benefit significantly from alcohol's cardioprotective effects. For those ages 30 to 59, the combined effects of alcohol-related injuries and alcohol-related diseases greatly outweigh alcohol's beneficial effects on the heart. Among those ages 60 to 69 , the beneficial and detrimental effects of alcohol are roughly balanced. Among those older than 70, alcohol's beneficial effects on the heart outweigh its many detrimental effects. However, some $70+$ year-olds will be taking medicines that may not mix well with alcohol, and some may have other conditions that make drinking especially risky. When considered from these perspectives, there seems to be little evidence to recommend drinking for health; alcohol should be enjoyed in moderation, with full appreciation of its risks. Consuming more than two drinks per day increases the risk of high blood pressure, hemorrhagic stroke, and some forms of heart disease [5, 26].

When looking at the mortality profiles for each of the many demographic groups that make up the population of San Francisco, it becomes evident that each group is unique, and much of this uniqueness probably comes from each group's relationship to alcohol. Studies in the medical literature confirm some of these associations. For example, a survey of Latino women in San Francisco [41] found that they drink far less than their White counterparts, which explains their lower rates of mortality from alcohol-attributable diseases and injuries. On the other hand, it has been shown that African American men living in extremely poor neighborhoods are at especially high risk for alcohol-related problems [24]. The mortality profile for each of the various neighborhood and ethnic groups can be evaluated while comparing it with Tables 5-7.

### 3.4.7 Comments for illicit drugs

Illicit Drugs. Illicit drugs contribute to premature mortality in a variety of ways, but quantification is more difficult than with tobacco or alcohol. The majority of drug poisoning deaths in this report can be attributed to illicit drugs. Alcohol in combination with cocaine or heroin is a common cause of drug overdose deaths [21].

Although the great majority of AIDS infections in San Francisco have historically been among gay men, intravenous drug use is an important route of transmission. In San Francisco in 1995, 10.4\% of new AIDS cases were directly attributed to injection drug use and another $10.6 \%$ of new cases occurred among males who might have contracted the virus either sexually (gay or bisexual) or by their injection of illicit drugs [47]. Nationally in 1995, $36 \%$ of AIDS cases were attributed either directly
or indirectly to injection drug use [8]. Transmission of HIV by injection drug use is increasing in San Francisco (more than $14 \%$ of cases in 1997), and has affected African Americans disproportionately (more than a quarter of AIDS cases over the course of the epidemic) [47]. Crack cocaine smoking is also an important risk for AIDS [15].

Other associations between illicit drugs and the leading causes of death are difficult to quantify. These include deaths from hepatitis or other infections transmitted during injection drug use, homicides committed in the course of illicit drug commerce, deaths from motor-vehicle traffic injuries, and suicides, to name a few.

### 3.5 Burden of deaths related to diet and physical inactivity

Dietary excess and physical inactivity are common in the developed regions of the world, and they contribute to several of the leading causes of death in those regions. San Francisco is no exception. The pages that follow present an analysis of deaths from Ischemic Heart Disease, Colorectal Cancer, and Breast Cancer. There are other risk factors for each of these causes of death, and other causes of death are associated with dietary excess and physical inactivity (see Tables 5-6). In particular, smoking, is an especially important risk for heart disease and stroke, but prevention of these two leading causes of premature death will be most effective if we also consider them in terms of their association with diet and physical inactivity.

A literature search is underway to determine the extent to which each of these causes of death can be attributed to
diet/physical inactivity:

- Ischemic Heart Disease. High-fat diet, physical inactivity, and overweight are well-established risks.
- Stroke. High-fat diet, physical inactivity, and overweight are well-established risks.
- Colorectal Cancer. Low-fiber diet and physical inactivity are well-established risks.
- Breast Cancer. Overweight and physical inactivity are well-established risks.
- Cardiomyopathies. This category includes congestive heart failure secondary to ischemic heart disease.
- Diabetes mellitus. Diabetes is a major risk for ischemic heart disease and stroke. Non-insulindependent diabetes mellitus, which is the most common type of diabetes, is highly correlated with overweight and physical inactivity.
- Falls. Physical inactivity is a risk, but so are many forms of exercise.
- Prostate Cancer. Physical inactivity is a risk; high-fat diet may be a risk.
- Nephritis \& Nephrosis. More than half of all cases are secondary to non-insulin-dependent diabetes mellitus.
- Uterine Cancer. Highly correlated with overweight.
- Hypertension. Hypertension, a major risk for stroke and ischemic heart disease, is highly correlated with overweight and physical inactivity.

### 3.5.1 Ischemic Heart Disease Deaths

For the period 1990 through 1995, 11010 San Francisco residents died from ischemic heart disease, an average of 1835 per year, and representing 141184 standard expected years of life lost (Table 39). There were 5548 male deaths, representing 87724 standard expected years of life lost, and 5462 female deaths, representing 53461 standard expected years of life lost. Average years of life lost per death was 16 years for males and 10 years for females, indicating that death from ischemic heart disease occurred at older ages. For both men and women, ischemic heart disease was the first or second leading cause of death in every ethnic group, and for ages 45 or older.

For males, ischemic heart disease was the first or second leading cause of death in 21 neighborhoods (47, p. 83). It was the third leading cause in one ZIP, 94124 (Bayview-Hunters Point). Among females, ischemic heart disease was the leading cause of female deaths in every San Francisco neighborhood (Table 48, p. 84).

The trends in ischemic heart disease mortality rates by sex and ethnicity for the period 1987 through 1995 are displayed in Figure 19. For males, African Americans had the significantly highest mortality rates throughout the three time periods. White males had the second highest ischemic heart disease mortality rates, significantly greater than the groups with the lowest rates, Asian and Latino males. Rates for all groups in 1993-1995 were less than in 1987-1989, but significantly so only for Whites. For females, the picture among the ethnicities is the same as it is for males, except that the low rates among Asian and Latino females remained flat over the periods. White females' rates also declined significantly.

Table 39: Burden of Ischemic Heart Disease Deaths by Age and Sex, and by Ethnicity and Sex 1990-1995

| Asian/other | 97.4 | $(91.2,103.6)$ | 0.56 | 43.4 | $(40.1,46.7)$ | 0.59 |  |  |  |  |  |  |

### 3.5.2 Colorectal Cancer Deaths

For the period 1990 through 1995, 1058 San Francisco residents died from colorectal cancer, an average of 176 per year, and representing 16967 standard expected years of life lost (Table 41). There were 520 male deaths, representing 9048 standard expected years of life lost, and 538 deaths representing 7919 standard expected years of life lost. Average years of life lost per death was 17 years for males and 15 years for females, indicating that death from colorectal cancer occurred at relatively older ages.

For males, colorectal cancer was the 13 th leading cause of death. It was the 11 th leading cause for Asians, and the 12 th leading cause for Filipinos and Whites. For females, colorectal cancer was the seventh leading cause of death. It was the fourth leading cause of death for Filipinos, sixth for Asians, eighth for Whites, and tenth for African Americans.

For males, colorectal cancer was among the ten leading causes of deaths in seven neighborhoods (Table 47, p. 83), including two in which it ranked seventh: 94116 (Parkside) and 94121 (Outer Richmond), and three in which it ranked eighth: 94122 (Sunset), 94123 (Marina), and 94132 (Lake Merced). For females, colorectal cancer was among the ten leading causes of deaths in 15 out of 22 neighborhoods. It was the fifth leading cause of death in ZIP code 94132 (Lake Merced) and the sixth leading cause of death in ZIP codes 94108 (Chinatown), 94112 (Ingleside-Excelsior / Crocker-Amazon), 94127 (St. Francis Wood, Miraloma / Seaside), and 94133 (North Beach / Chinatown) (Table 47, p. 83).

*Rate per 100000 per year, age-adjusted to 1940 U.S. standard million population

### 3.5.3 Breast Cancer Deaths

For the period 1990 through 1995, 722 San Francisco female residents died from breast cancer, an average of 120 per year, and representing 15218 standard expected years of life lost (Table 43). The average years of life lost per death was 21 .

Breast cancer was the fourth leading cause of female deaths overall, the third leading cause for ages 25 to 44 , the second leading cause for ages 45 to 64 , and the sixth leading cause for ages 65 or older. It was among the five leading causes of death for all ethnic groups.

In 18 out of 22 San Francisco neighborhoods, breast cancer was among the five leading causes of female deaths. Breast cancer was the second leading cause of female deaths in ZIP code 94124 (Bayview-Hunters Point); the third leading cause of death in ZIP codes 94112 (Castro, Noe Valley), 94121 (Outer Richmond), 94131 (Twin Peaks-Glenn Park), and 94132 (Lake Merced); and the fourth leading cause in other ZIP codes (Table 48, p. 84).

The trends in female breast cancer mortality rates by ethnicity for the period 1987 through 1995 are displayed in Figure 21. African Americans and Whites had the highest rates in 1987-1989; by 1993-1995, only the White rate had declined. Latinos and Asians rates started much lower and stayed at that level throughout the time studied.

Table 43: Burden of Female Breast Cancer Deaths, by Age and Ethnicity, 1990-1995

### 3.5.4 Comments

Nationally, diet/inactivity accounts for an estimated $14 \%$ of mortality, making it the second leading preventable cause of death [35]. Tables 5-7 depict the ways in which diet/inactivity contribute to the leading causes of death in San Francisco.

Overweight. Diet/inactivity is an awkward expression for the relationship between poor diet (too much fat, too many calories, not enough fresh fruits and vegetables) and physical inactivity. It is manifested as overweight. In 1995, $28.6 \%$ of Americans and $26.4 \%$ of Californians were overweight [43]. We do not have specific data for San Francisco, but it is unlikely that we are much better off than other Californians. Although a decrease in overweight is a national health priority for the year 2000, the prevalence of overweight has been increasing rather than decreasing [13]. The greatest burden of overweight nationally is among women of color; nearly half of African American and Latino women are overweight [28]. Overweight increases the risk of death from ischemic heart disease, stroke, and some cancers. Among non-smoking adults between the ages of 30 and 74 , the risk of death from all causes increases as body weight increases, even at weights below those usually considered as overweight, especially among younger people [51].

Exercise. According to the recent Surgeon General's Report on Physical Activity and Health [13], the risk of ischemic heart disease, one of the leading causes of death in San Francisco, is $80 \%$ higher among those who are the least physically active, compared with those who are most active. In addition, exercise decreases the risk of high blood pressure [13], diabetes [31, 32, 55, 13], stroke [1, 19], colon cancer $[20,56,33,49,29]$, breast cancer [36, 18, 10], and prostate cancer [9]. Even modest exercise such as stair climbing, walking, and moderately vigorous sports play will decrease the risk of premature mortality [39, 40]. In a study of retired non-smoking men, walking more than 2 miles per day was associated with a $50 \%$ reduction in the mortality rate, compared with those who walked less than a 1 mile per day [23]. Those who adopt healthy life-styles (exercising, not smoking, avoiding overweight) not only live longer, they also experience less disability in old age [53].

### 3.6 Ethnicity Profiles

The race/ethnicity variable in the death certificate records had seven common categories available across all six years: White, African American, Latino, Asian/Pacific Islander, Filipino, Native American, and Other. San Francisco's 13 leading causes of premature death were ranked for each ethnic group (Table 45), and the leading causes of premature mortality for each ethnic group are shown in the pages that follow (except for the 192 deaths classified as Other).

Table 45: Ranking of Leading Causes of Deaths by Ethnicity and Sex 1990-1995

### 3.6.1 African-American

Standardized Expected Years of Life Lost (SEYLL) - African American

Figure 22: Leading causes of death for African American males (top) and females (bottom), 1990-1995. For all causes, there were 3739 male deaths (SEYLL $=113634$ years) and 2540 female deaths (SEYLL $=55490$ years). The 1990 Census population estimate was 76944 ( $10.6 \%$ of total population).

Among African American males: AIDS was the leading cause of death, representing $24.1 \%$ of the 113634 expected years of life lost from all causes. AIDS, ischemic heart disease ( $11.8 \%$ ), and homicide $(9.3 \%)$ accounted for over $45 \%$ of all expected years of life lost. The most premature causes were homicide, MV-traffic , suicide, AIDS, and drug poisoning, causing an average of 53, 52, 47, 44, and 42 expected years of life lost per death, respectively. Injuries were the third, fourth, eighth, and tenth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, stroke, pneumonia), alcohol with seven (homicide, drug poisoning, stroke, pneumonia, MV-traffic, cardiomyopathies, suicide), drug use with six (AIDS, homicide, drug poisoning, stroke, MV-traffic, suicide) and diet/physical inactivity with two (ischemic heart disease, stroke).

Among African American females: Ischemic heart disease was the leading cause of death, representing $16.2 \%$ of the 55490 expected years of life lost from all causes. AIDS was the second leading cause ( $6.9 \%$ of all expected years of life lost). The most premature causes were homicide, drug poisoning, and AIDS, causing an average of 51,45 , and 44 expected years of life lost per death, respectively. Injuries were the sixth and seventh leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, and colorectal cancer), alcohol with six (stroke, breast cancer, drug poisoning, homicide, pneumonia, colorectal cancer), drug use with four (AIDS, stroke, drug poisoning, homicide) and diet/physical inactivity with five (ischemic heart disease, stroke, breast cancer, diabetes mellitus, colorectal cancer).

### 3.6.2 Asian/Pacific Islander

Standardized Expected Years of Life Lost (SEYLL) - Asian/P.I.

Figure 23: Leading causes of death for Asian/Pacific Islander males (top) and females (bottom), 1990-1995. For all causes, there were 3476 male deaths (SEYLL $=71031$ years) and 2880 female deaths (SEYLL $=44511$ years). The 1990 Census population estimate was $166480(23.0 \%$ of total population).

Among Non-Filipino Asian/Pacific Island males: Ischemic heart disease was the leading cause of death, representing $16.9 \%$ of the 71031 expected years of life lost from all causes, followed by lung cancer ( $7.7 \%$ ), AIDS ( $6.6 \%$ ) and stroke ( $6.0 \%$ ), and together accounted for over one-third of years of life lost. The most premature causes were homicide, AIDS, MV-traffic, and suicide, causing an average of $57,45,42$ and 40 expected years of life lost per death, respectively. Injuries were the sixth, seventh and tenth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, chronic obstructive pulmonary disease, and pneumonia,), alcohol with four (stroke, homicide, suicide, MV-traffic), drug use with five (AIDS, stroke, homicide, suicide, MV-traffic), and diet/physical inactivity with two (ischemic heart disease, stroke).

Among Non-Filipino Asian/Pacific Island females: Ischemic heart disease was the leading cause of death, representing $15.2 \%$ of the 44511 expected years of life lost from all causes, followed by stroke ( $10.3 \%$ ), lung cancer ( $6.2 \%$ ) and breast cancer ( $5.5 \%$ ), and together accounted for over one-third of years of life lost. The most premature causes were MV-traffic and suicide, causing an average of 35 and 31 expected years of life lost per death, respectively. Injuries were the seventh and eighth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, colorectal cancer), alcohol with six (stroke, breast and colorectal cancer, suicide, MV-traffic, pneumonia), drug use with three (stroke, suicide, MV-traffic) and diet/physical inactivity with five (ischemic heart disease, stroke, breast and colorectal cancer, and diabetes mellitus).

### 3.6.3 Filipino

Figure 24: Leading causes of death for Filipino males (top) and females (bottom), 1990-1995. For all causes, there were 1020 male deaths $(S E Y L L=19801$ years) and 571 female deaths $(S E Y L L=10875$ years). The 1990 Census population estimate was 40977 ( $5.7 \%$ of total population).

Among Filipino males: Ischemic heart disease was the leading cause of death, representing $22.3 \%$ of the 19801 expected years of life lost from all causes. Ischemic heart disease and AIDS (12.4\%) accounted for one-third of all expected years of life lost. The most premature causes were congenital anomalies, homicide, AIDS and MV-traffic, causing an average of $63,56,46$ and 41 expected years of life lost per death, respectively. Injuries were the fifth and sixth leading cause of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, and chronic obstructive pulmonary disease), alcohol with four (stroke, MV-traffic, homicide, liver cancer), drug use with four (AIDS, stroke, MV-traffic, homicide), and diet/physical inactivity with two (ischemic heart disease, stroke).

Among Filipino females: Ischemic heart disease was the leading cause of death, representing $17.4 \%$ of the 10875 expected years of life lost from all causes. Ischemic heart disease, stroke ( $9.9 \%$ ) and breast cancer ( $6.3 \%$ ) accounted for over one-third of all expected years of life lost. AIDS was the 10th leading cause (six deaths, $2.1 \%$ of expected years of life lost). The most premature causes were congenital anomalies and AIDS, causing an average of 61 and 38 expected years of life lost per death, respectively. No injury categories were among the ten leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, colorectal cancer, and pneumonia), alcohol with four (stroke, breast cancer, colorectal cancer, pneumonia), drug use with two (stroke, AIDS) and diet/physical inactivity with five (ischemic heart disease, stroke, breast cancer, colorectal cancer, diabetes mellitus).

### 3.6.4 Latino

Figure 25: Leading causes of death for Latino males (top) and females (bottom), 1990-1995. For all causes, there were 2195 male deaths (SEYLL $=75741$ years) and 1217 female deaths (SEYLL $=$ 22086 years). The 1990 Census population estimate was 96640 ( $13.3 \%$ of total population).

Among Latino males: AIDS was the leading cause of death, representing $38.7 \%$ of the 75741 expected years of life lost from all causes. AIDS, homicide (7.1\%), and ischemic heart disease (6.5\%) accounted for over one-half all expected years of life lost. The most premature causes were homicide, MV-traffic, suicide, AIDS, drug poisoning, and alcohol use (psychiatric diagnosis), causing an average of $57,52,48,46,46$ and 41 expected years of life lost per death, respectively. Injuries were the second, fourth, sixth, and seventh leading causes of death. Tobacco was associated with three leading causes (ischemic heart disease, stroke, and pneumonia), alcohol with eight (homicide, drug poisoning, cirrhosis, suicide, MV-traffic, alcohol [psychiatric diagnosis], stroke, pneumonia), drug use with six (AIDS, homicide, drug poisoning, cirrhosis, suicide, MV-traffic) and diet/physical inactivity with two (ischemic heart disease, stroke).

Among Latino females: Ischemic heart disease was the leading cause of death, representing $14.4 \%$ of the 22086 expected years of life lost from all causes. AIDS was the second leading cause $(4.9 \%$ of all expected years of life lost). The most premature causes were congenital anomalies, homicide, and AIDS, causing an average of 72,56 , and 50 expected years of life lost per death, respectively. Injuries were the ninth leading cause of death (homicide). Tobacco was associated with four leading causes (ischemic heart disease, stroke, pneumonia, lung cancer), alcohol with five (stroke, breast cancer, cirrhosis, pneumonia, homicide), drug use with four (AIDS, stroke, cirrhosis, homicide) and diet/physical inactivity with five (ischemic heart disease, stroke, breast cancer, lung cancer, diabetes mellitus).

### 3.6.5 Native American

Figure 26: Leading causes of death for Native American males (top) and females (bottom), 1990-1995. For all causes, there were 76 male deaths $(\mathrm{SEYLL}=3031$ years) and 26 female deaths $(\mathrm{SEYLL}=800$ years). The 1990 Census population estimate was 2464 ( $0.3 \%$ of total population).

Among Native American males: AIDS was the leading cause of death, representing $44.1 \%$ of the 3031 expected years of life lost from all causes. AIDS, cirrhosis ( $11.7 \%$ ) and drug poisoning ( $6.6 \%$ ) accounted for over $60 \%$ of total SEYLL. The most premature causes (and with at least five deaths) were also AIDS and cirrhosis, causing an average of 48 and 44 expected years of life lost per death, respectively. (Other causes involved very small numbers of deaths, but with unusually high average years of life lost.) Injuries were the third, sixth, seventh, and ninth leading causes of death. Tobacco was associated with three leading causes (ischemic heart disease, stroke, lung cancer), alcohol with six (cirrhosis, drug poisoning, alcohol use [psychiatric diagnosis], homicide, stroke, and falls), drug use with five (AIDS, cirrhosis, drug poisoning, homicide, stroke) and diet/physical inactivity with three (ischemic heart disease, stroke, lung cancer).

Among Native American females: Chronic liver disease was the leading cause of death, representing $23.6 \%$ of the 800 expected years of life lost from all causes, and was the only leading cause with more than four deaths. It was associated with an average of 38 expected years of life lost per death. Injuries were the second and eighth leading causes of death. Only the first three causes had more than one death; of these, cirrhosis and drug poisoning are associated with alcohol and drugs, and ischemic heart disease with tobacco, diet and physical inactivity.

### 3.6.6 White

Figure 27: Leading causes of death for White males (top) and females (bottom), 1990-1995. For all causes, there were 17972 male deaths $(S E Y L L=489287$ years) and 12520 female deaths (SEYLL $=$ 156398 years). The 1990 Census population estimate was 338923 ( $46.8 \%$ of total population).

Among White males: AIDS was the leading cause of death, representing $46.2 \%$ of the 489287 expected years of life lost from all causes, followed by ischemic heart disease ( $10.7 \%$ ), and together accounted for over $57 \%$ of years of life lost. The most premature causes were drug poisoning, AIDS, suicide, alcohol use (psychiatric diagnosis) and cirrhosis, causing an average of 46, 44, and 38, 34 and 32 expected years of life lost per death, respectively. Injuries were the third and fourth leading cause of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, pneumonia, stroke, and chronic obstructive pulmonary disease), alcohol with five (suicide, drug poisoning, cirrhosis, stroke, alcohol use [psychiatric diagnosis]), drug use with five (AIDS, suicide, drug poisoning, cirrhosis, stroke) and diet/physical inactivity with two (ischemic heart disease, stroke).

Among White females: Ischemic heart disease was the leading cause of death, representing $20.7 \%$ of the 156398 expected years of life lost from all causes. The most premature causes were drug poisoning and suicide, causing an average of 43 and 33 expected years of life lost per death, respectively. Injuries were the seventh and ninth leading causes of death. Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, chronic obstructive pulmonary disease, and colorectal cancer), alcohol with seven (stroke, breast cancer, pneumonia, chronic obstructive pulmonary disease, colorectal cancer, drug poisoning, cirrhosis), drug use with four (stroke, suicide, drug poisoning, cirrhosis) and diet/physical inactivity with five (ischemic heart disease, stroke, breast cancer, diabetes mellitus, colorectal cancer).

### 3.7 Neighborhood profiles

Table 46: San Francisco Neighborhoods by ZIP code and 1990 Census Population

| ZIP code | Neighborhood | African American | Asian /P.I. | Latino | White | Other | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 94102 | Hayes Valley / Tenderloin / N. of Market | 5566 | 6625 | 2625 | 11769 | 208 | 26793 |

[^24]

San Francisco is composed of many local neighborhoods. There is no common agreement on how to draw neighborhood boundaries and, in any case, they shift over time with migration, housing and commercial changes, and development practices. We divided the City into local areas based on United Postal ZIP codes. ZIP code areas are fairly large and stable, many neighborhoods are roughly approximated by their ZIP codes, permanently housed residents know their ZIP codes, and ZIP codes are the smallest geographic area commonly available in health data (including mortality data used in these analyses).

San Francisco neighborhoods, ZIP codes, and 1990 census population by ethnicity are summarized in Table 46. An accompanying map shows the geographic boundaries. Three small downtown ZIP code areas were combined: 94104, 94105, and 94111; all together they constitute the smallest area. Two others, 94129 (Presidio) and 94130 (Treasure Island), were military bases that closed in the 1990s; these were categorized as "other."

San Francisco's overall 13 leading causes of death (includes the top ten leading causes for males and females) were ranked in each ZIP code based on standard expected years of life lost (SEYLL) (Tables 47 and 48). For example, for males in ZIP code 94121 (Outer Richmond), AIDS was the second leading cause of death, ischemic heart disease was the first leading cause, drug poisoning was 14 th, and so on. Chronic liver disease was not among the top 20 causes of premature death for males in that ZIP code.

These tables can be read across, by row, to review the ranking of these specific causes for a given neighborhood, or down, by column, to see the relative importance to premature mortality of a given cause across the neighborhoods of San Francisco. For example, male suicide is among the top 10 causes in all but one ZIP (94134, where it is cause number 11), but among females is not among the top 10 in 10 areas (out of 22 ), including four in which it is not even in the top 20. Ischemic heart disease was the leading cause of death in every ZIP code for females, and ranked first or second in every ZIP code among males. AIDS was also ranked the first or second leading cause of death among males in every ZIP code, while among females it was among the top 10 in only nine ZIP codes and it is not among the top 20 in seven. ZIP code 94124 (Bayview Hunters-Point) was the only neighborhood where homicide was the first leading cause of death among males.

One thousand sixty-six deaths occurred to persons with an unknown ZIP code: 786 male deaths and 280 female deaths. We do not know at this time to what extent the leading causes of death in this groups is representative of persons who were homeless when they died.

Following the summary Tables 47 and 48 are profiles of each neighborhood area, as defined by ZIP code. The narrative summary links the neighborhood's leading causes of death to the underlying contributing factors presented in the prevention attribution matrixes (Tables 6-7, pages 24-25). In considering the possible roles of these determinants to leading causes of premature mortality for a specific neighborhoods, readers may want to refer back to these tables and the other discussions of attributable factors in this report.

Table 47: Ranking of Leading Causes of Deaths by Zip Code, Male Residents 1990-1995

| ZIP code | SEYLL | Deaths | $\begin{gathered} \mathrm{A} \\ \mathrm{I} \\ \mathrm{D} \\ \mathrm{~S} \end{gathered}$ | $\begin{gathered} \mathrm{H} \\ \mathrm{E} \\ \mathrm{~A} \\ \mathrm{R} \\ \mathrm{~T} \\ \\ \mathrm{D} \\ \mathrm{I} \\ \mathrm{~S} \\ \mathrm{E} \\ \mathrm{~A} \\ \mathrm{~S} \\ \mathrm{E} \\ \hline \end{gathered}$ | L <br> U <br> N <br> G <br> C <br> A <br> N <br> C <br> E <br> R | $\begin{gathered} \mathrm{S} \\ \mathrm{~T} \\ \mathrm{R} \\ \mathrm{O} \\ \mathrm{~K} \\ \mathrm{E} \end{gathered}$ | D <br> R <br> U <br> G <br> P <br> O <br> I <br> S <br> O <br> N | $\begin{gathered} \mathrm{S} \\ \mathrm{U} \\ \mathrm{I} \\ \mathrm{C} \\ \mathrm{I} \\ \mathrm{D} \\ \mathrm{E} \end{gathered}$ | $\begin{gathered} \mathrm{H} \\ \mathrm{O} \\ \mathrm{M} \\ \mathrm{I} \\ \mathrm{C} \\ \mathrm{I} \\ \mathrm{D} \\ \mathrm{E} \end{gathered}$ | $\begin{gathered} \mathrm{P} \\ \mathrm{~N} \\ \mathrm{E} \\ \mathrm{U} \\ \mathrm{M} \\ \mathrm{O} \\ \mathrm{~N} \\ \mathrm{I} \\ \mathrm{~A} \end{gathered}$ | C <br> H <br> R <br> O <br> N <br> I C <br> L <br> I <br> V <br> E <br> R | $\begin{aligned} & \mathrm{C} \\ & \mathrm{O} \\ & \mathrm{P} \\ & \mathrm{D} \end{aligned}$ | M <br> O <br> T <br> O <br> R <br> V <br> E <br> H <br> I <br> C <br> L <br> E | C O L O N C A N C E R |

### 3.7.1 Hayes Valley/Tenderloin/North of Market (94102)

Figure 28: Leading causes of death for Hayes Valley/Tenderloin/N. of Market (94102) males (top) and females (bottom), 1990-1995. For all causes, there were 2255 male deaths (SEYLL $=74482$ years) and 599 female deaths (SEYLL $=13201$ years). The 1990 Census population estimate was 26793 (3.7\% of total population).

Among males in 94102: AIDS was the leading cause of death, representing $41.4 \%$ of the 74482 expected years of life lost from all causes, followed by ischemic heart disease (10.1\%), drug poisoning ( $5.8 \%$ ) and cirrhosis (4.1\%), and together accounted for over $60 \%$ of years of life lost. The most premature causes were drug poisoning, homicide, AIDS, and suicide, causing an average of 46, 46, 45, and 41 expected years of life lost per death, respectively. Injuries were the third, sixth, and ninth leading cause of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, pneumonia, and stroke), alcohol with seven (drug poisoning, cirrhosis, alcohol use [psychiatric diagnosis], suicide, pneumonia, homicide, stroke), drug use with six (AIDS, drug poisoning, cirrhosis, suicide, homicide, stroke) and diet/physical inactivity with two (ischemic heart disease, stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $16.3 \%$ of the 13201 expected years of life lost from all causes, followed by AIDS (6.4\%), and drug poisoning (6.1\%), together accounted for over one-fourth of years of life lost. The most premature causes were drug poisoning, AIDS, suicide and cirrhosis, causing an average of $45,44,37$ and 33 expected years of life lost per death, respectively. Injuries were the third and seventh leading cause of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, and colorectal cancer), alcohol with six (drug poisoning, stroke, cirrhosis, pneumonia, breast cancer, colorectal cancer), drug use with five (AIDS, drug poisoning, stroke, cirrhosis, suicide) and diet/physical inactivity with five (ischemic heart disease, stroke, lung and breast cancer, colorectal cancer).

### 3.7.2 South of Market (94103)

Figure 29: Leading causes of death for South of Market (94103) males (top) and females (bottom), 1990-1995. For all causes, there were 1196 male deaths (SEYLL $=38526$ years) and 382 female deaths (SEYLL $=7231$ years). The 1990 Census population estimate was 17813 ( $2.5 \%$ of total population).

Among males in 94103: AIDS was the leading cause of death, representing $39.3 \%$ of the 38526 expected years of life lost from all causes, followed by ischemic heart disease ( $11.0 \%$ ), drug poisoning ( $8.8 \%$ ), and suicide ( $4.0 \%$ ). The most premature causes were drug poisoning, homicide, AIDS, suicide, alcohol use (psychiatric diagnosis), and cirrhosis, causing an average of 46, 45, 44, 38, 37 and 35 expected years of life lost per death, respectively. Injuries were the third, fourth, and seventh leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, pneumonia, and chronic obstructive pulmonary disease), alcohol with six (drug poisoning, suicide, alcohol use [psychiatric diagnosis], cirrhosis, homicide, pneumonia), drug use with six (AIDS, drug poisoning, suicide, alcohol use [psychiatric diagnosis], cirrhosis, homicide) and diet/physical inactivity with two (ischemic heart disease, lung cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $19.2 \%$ of the 7231 expected years of life lost from all causes, followed by drug poisoning ( $7.4 \%$ ), stroke ( $6.8 \%$ ) and cirrhosis (5.7\%). The most premature causes were homicide, drug poisoning, and cirrhosis, causing an average of 46,44 , and 37 expected years of life lost per death, respectively. Injuries were the second, fifth, and eighth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, stroke, pneumonia, lung cancer), alcohol with seven (drug poisoning, stroke, cirrhosis, homicide, pneumonia, suicide, breast cancer), drug use with five (drug poisoning, stroke, cirrhosis, homicide, suicide) and diet/physical inactivity with five (ischemic heart disease, stroke, lung and breast cancer, diabetes mellitus).

### 3.7.3 Potrero Hill (94107)

Figure 30: Leading causes of death for Potrero Hill (94107) males (top) and females (bottom), 19901995. For all causes, there were 636 male deaths (SEYLL $=20113$ years) and 283 female deaths (SEYLL $=4773$ years). The 1990 Census population estimate was 11977 ( $1.7 \%$ of total population).

Among males in 94107: AIDS was the leading cause of death, representing $45.3 \%$ of the 20113 expected years of life lost from all causes. AIDS, ischemic heart disease ( $8.4 \%$ ), and drug poisoning ( $5.3 \%$ ) accounted for $59 \%$ of all expected years of life lost. The most premature causes were sudden infant deaths syndrome (SIDS), homicide, suicide, drug poisoning and AIDS, causing an average of $82,57,47,46$ and 44 expected years of life lost per death, respectively. Injuries were the third, fourth, and fifth leading causes of death. Tobacco was associated with three leading causes (ischemic heart disease, lung cancer, SIDS), alcohol with five (drug poisoning, homicide, suicide, cirrhosis, alcohol use [psychiatric diagnosis]), drug use with six (AIDS, drug poisoning, homicide, suicide, cirrhosis, alcohol use/psychiatric) and diet/physical inactivity with one (ischemic heart disease).

Among females: Ischemic heart disease was the leading cause of death, representing $14.9 \%$ of the 4773 expected years of life lost from all causes. Ischemic heart disease, drug poisoning ( $7.6 \%$ ), stroke ( $7.0 \%$ ) and breast cancer ( $5.0 \%$ ) accounted for $35 \%$ of all expected years of life lost. The most premature causes were drug poisoning, homicide, and AIDS, causing an average of 45,42 , and 33 expected years of life lost per death. Injuries were the second and tenth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, stroke, pneumonia, lung cancer), alcohol with six (drug poisoning, stroke, breast cancer, pneumonia, cardiomyopathy, homicide), drug use with five (drug poisoning, stroke, AIDS, cardiomyopathy, homicide) and diet/physical activity with four (ischemic heart disease, stroke, breast cancer, cardiomyopathy).

### 3.7.4 Chinatown (94108)

Figure 31: Leading causes of death for Chinatown (94108) males (top) and females (bottom), 19901995. For all causes, there were 548 male deaths (SEYLL $=10766$ years) and 442 female deaths $(\mathrm{SEYLL}=5380$ years). The 1990 Census population estimate was 14230 ( $2.0 \%$ of total population).

Among males in 94108: AIDS was the leading cause of death, representing $22.6 \%$ of the 10766 expected years of life lost from all causes. AIDS, ischemic heart disease ( $16.1 \%$ ) and suicide ( $5.1 \%$ ) accounted for $44 \%$ of all expected years of life lost. The most premature causes were AIDS, drug poisoning, and suicide, causing an average of 43,42 and 34 expected years of life lost per death, respectively. Injuries were the third and eighth leading cause of death. Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, chronic obstructive pulmonary disease, pneumonia, colorectal cancer), alcohol with six (suicide, stroke, pneumonia, drug poisoning, cirrhosis, colorectal cancer), drug use with five (AIDS, suicide, stroke, drug poisoning, cirrhosis) and diet/physical inactivity with three (ischemic heart disease, stroke, colorectal cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $23.6 \%$ of the 5380 expected years of life lost from all causes. Ischemic heart disease, stroke (9.1\%), and lung cancer (7.7\%) together accounted for $40 \%$ of all expected years of life lost. The most premature cause was AIDS, causing an average of 45 expected years of life lost per death. No injuries were among the leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, colorectal cancer), alcohol with five (stroke, pneumonia, and breast, colorectal and liver cancer), drug use with two (stroke, AIDS) and diet and physical inactivity with five (ischemic heart disease, stroke, breast and colorectal cancers, and diabetes mellitus).

### 3.7.5 Polk/Russian Hill (94109)

Figure 32: Leading causes of death for Polk/Russian Hill (94109) males (top) and females (bottom), 1990-1995. For all causes, there were 2418 male deaths (SEYLL $=66536$ years) and 1681 female deaths (SEYLL $=22046$ years). The 1990 Census population estimate was 49482 ( $6.8 \%$ of total population).

Among males in 94109: AIDS was the leading cause of death, representing $40.1 \%$ of the 66536 expected years of life lost from all causes. AIDS, ischemic heart disease ( $10.7 \%$ ), and suicide ( $5.1 \%$ ) accounted for $56 \%$ of all expected years of life lost. The most premature causes were homicide, AIDS, drug poisoning, and suicide, causing an average of $48,44,43$, and 39 expected years of life lost per death, respectively. Injuries were the third, fifth and tenth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, pneumonia, stroke, chronic obstructive pulmonary disease), alcohol with six (suicide, drug poisoning, pneumonia, stroke, cirrhosis, homicide), drug use with six (AIDS, suicide, drug poisoning, stroke, cirrhosis, homicide) and diet/physical inactivity with two (ischemic heart disease, stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $19.7 \%$ of the 22046 expected years of life lost from all causes. Ischemic heart disease, stroke ( $6.5 \%$ ), lung cancer ( $5.9 \%$ ) and breast cancer ( $5.4 \%$ ) accounted for $38 \%$ of all expected years of life lost. The most premature causes were suicide and cirrhosis, causing an average of 31 and 30 expected years of life lost per death, respectively. Injuries were the seventh leading cause of death (suicide). Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, colorectal cancer), alcohol with five (stroke, breast cancer, pneumonia, colorectal cancer, and cirrhosis), drug use with two (stroke, suicide), and diet/physical inactivity with five (ischemic heart disease, stroke, breast and colorectal cancers, and diabetes mellitus).

### 3.7.6 Inner Mission/Bernal Heights (94110)

Figure 33: Leading causes of death for Inner Mission/Bernal Heights (94110) males (top) and females (bottom), 1990-1995. For all causes, there were 2214 male deaths (SEYLL $=68597$ years) and 1280 female deaths (SEYLL $=23360$ years). The 1990 Census population estimate was 71118 ( $9.8 \%$ of total population).

Among males in 94110: AIDS was the leading cause of death, representing $38.5 \%$ of the 68597 expected years of life lost from all causes, followed by ischemic heart disease (9.4\%), and homicide (5.0\%). The most premature causes were homicide, MV-traffic, drug poisoning, AIDS, and suicide, causing an average of $59,51,48,45$, and 43 expected years of life lost per death, respectively. Injuries were the third, fourth, fifth, and eighth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, stroke, pneumonia), alcohol with seven (homicide, drug poisoning, suicide, cirrhosis, MV-traffic, stroke, pneumonia), drug use with seven (AIDS, homicide, drug poisoning, suicide, cirrhosis, MV-traffic, stroke,) and diet/physical inactivity with two (ischemic heart disease, stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $15.4 \%$ of the 23360 expected years of life lost from all causes, followed by stroke ( $6.3 \%$ ) and AIDS ( $5.8 \%$ ). The most premature causes were AIDS, drug poisoning, MV-traffic, and suicide, causing an average of 49, 46, 44 and 44 expected years of life lost per death, respectively. Injuries were the sixth, ninth and tenth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, colorectal cancer), alcohol with seven (stroke, breast cancer, drug poisoning, pneumonia, colorectal cancer, MV-traffic, suicide), drug use with five (stroke, AIDS, drug poisoning, MV-traffic, suicide) and diet/physical inactivity with four (ischemic heart disease, stroke, breast and colorectal cancer).

### 3.7.7 Rincon/Telegraph Hill/Embarcadero (94104, -05, -11)

Figure 34: Leading causes of death for Rincon/Telegraph Hill/Embarcadero (94104, -05, -11) males (top) and females (bottom), 1990-1995. For all causes, there were 214 male deaths (SEYLL $=5475$ years) and 118 female deaths (SEYLL $=1683$ years). The 1990 Census population estimate was 5830 ( $0.8 \%$ of total population).

Among males in 94104/05/11: AIDS was the leading cause of death, representing $26.8 \%$ of the 5475 expected years of life lost from all causes, followed by ischemic heart disease ( $17.1 \%$ ), lung cancer ( $8.5 \%$ ) and suicide ( $5.3 \%$ ). The most premature causes were MV-traffic, homicide, AIDS, and drug poisoning, causing an average of $58,51,45$, and 39 expected years of life lost per death, respectively. Injuries were the fourth, sixth, eighth and tenth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, stroke, pneumonia), alcohol with seven (suicide, stroke, drug poisoning, cirrhosis, motor vehicle-traffic, pneumonia, homicide), drug use with seven (AIDS, suicide, stroke, drug poisoning, cirrhosis, motor vehicle-traffic, homicide), and diet/physical inactivity with two (ischemic heart disease, stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $18.9 \%$ of the 1683 expected years of life lost from all causes, followed by ovarian cancer ( $8.7 \%$ ). The most premature causes were birth trauma (one death), suicide and brain cancer (three deaths each), which caused an average of 82,41 and 36 expected years of life lost per death, respectively. Injuries were the third leading cause of death (suicide). Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, colorectal cancer, chronic obstructive pulmonary disease), alcohol with four (suicide, stroke, breast cancer, colorectal cancer), drug use with two (suicide, stroke), and diet/physical inactivity with four (ischemic heart disease, stroke, breast cancer, colorectal cancer).

### 3.7.8 Ingleside-Excelsior/Crocker-Amazon (94112)

Standardized Expected Years of Life Lost (SEYLL) - (94112)

Figure 35: Leading causes of death for Ingleside-Excelsior/Crocker-Amazon (94112) males (top) and females (bottom), 1990-1995. For all causes, there were 2072 male deaths (SEYLL $=45039$ years) and 2044 female deaths (SEYLL $=28000$ years). The 1990 Census population estimate was 64318 ( $8.9 \%$ of total population).

Among males in 94112: Ischemic heart disease was the leading cause of death, representing $17.7 \%$ of the 45039 expected years of life lost from all causes. Ischemic heart disease and AIDS (13.8\%) accounted for one-third of all expected years of life lost. The most premature causes were homicide, MV-traffic, AIDS, and suicide, causing an average of $57,56,44$ and 41 expected years of life lost per death, respectively. Injuries were the third, fifth and seventh leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, colorectal cancer), alcohol with seven (homicide, MV-traffic, stroke, suicide, pneumonia, colorectal cancer, cirrhosis), drug use with six (AIDS, homicide, MV-traffic, stroke, suicide, cirrhosis) and diet/physical inactivity with three (ischemic heart disease, stroke, colorectal cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $21 \%$ of the 28000 expected years of life lost from all causes. Ischemic heart disease, stroke ( $8.8 \%$ ), and breast cancer $(5.5 \%)$ together accounted for $35 \%$ of all expected years of life lost. The most premature causes were congenital anomalies, homicide, suicide and AIDS, causing an average of $63,55,47$ and 46 expected years of life lost per death, respectively. Injuries were the seventh and eighth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, colorectal cancer), alcohol with six (stroke, breast cancer, pneumonia, colorectal cancer, suicide, homicide), drug use with four (stroke, suicide, homicide, AIDS), and diet/physical inactivity with four (ischemic heart disease, stroke, breast cancer, colorectal cancer).

|  | xpected | f Life Lo | LL) - (9 |  |  |  |

Figure 36: Leading causes of death for Castro, Noe Valley (94114) males (top) and females (bottom), 1990-1995. For all causes, there were 2408 male deaths (SEYLL $=91868$ years) and 560 female deaths $(S E Y L L=8115$ years). The 1990 Census population estimate was 30577 ( $4.2 \%$ of total population).

Among males in 94114: AIDS deaths represented $75.4 \%$ of the 91868 expected years of life lost from all causes. AIDS, ischemic heart disease ( $3.1 \%$ ), and suicide ( $2.4 \%$ ) accounted for $81 \%$ of all expected years of life lost. The most premature causes were drug poisoning, suicide, AIDS, hepatitis, lymphomas, alcohol use (psychiatric diagnosis), and cirrhosis, which caused an average of 46, 45, 44, $43,37,35$, and 34 expected years of life lost per death, respectively. Injuries were the third and sixth leading causes of death. Tobacco was associated with three leading causes (ischemic heart disease, lung cancer, pneumonia), alcohol with five (suicide, cirrhosis, pneumonia, drug poisoning, alcohol use [psychiatric diagnosis]), drug use with five (AIDS, suicide, hepatitis, cirrhosis, drug poisoning), and diet/physical inactivity with one (ischemic heart disease).

Among females: Ischemic heart disease was the leading cause of death, representing $15.3 \%$ of the 8115 expected years of life lost from all causes. Ischemic heart disease, lung cancer ( $7.4 \%$ ), stroke ( $5.9 \%$ ) and breast cancer ( $5.4 \%$ ) accounted for a one-third of all expected years of life lost. The most premature causes were MV-traffic, drug poisoning, and AIDS, causing an average of 56, 53, and 43 expected years of life lost per death, respectively. Injuries were the eighth leading cause of death (MV-traffic). Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, chronic obstructive pulmonary disease), alcohol with five (stroke, breast cancer, pneumonia, MV-traffic, drug poisoning), drug use with four (stroke, AIDS, MV-traffic, drug poisoning) and diet/physical inactivity with four (ischemic heart disease, stroke, breast cancer, diabetes mellitus).

### 3.7.10 Western Addition/Japantown (94115)

Standardized Expected Years of Life Lost (SEYLL) - (94115)

Figure 37: Leading causes of death for Western Addition/Japantown (94115) males (top) and females (bottom), 1990-1995. For all causes, there were 1325 male deaths (SEYLL $=36198$ years) and 1144 female deaths (SEYLL = 16712 years). The 1990 Census population estimate was 28660 (4.0\% of total population).

Among males in 94115: AIDS was the leading cause of death, representing $40.9 \%$ of the 36198 expected years of life lost from all causes. AIDS and ischemic heart disease (10.5\%) accounted for $51 \%$ of all expected years of life lost. The most premature causes were homicide, AIDS, drug poisoning,suicide, and cirrhosis, causing an average of $50,43,43,40$, and 35 expected years of life lost per death, respectively. Injuries were the fourth, fifth, and sixth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, stroke, pneumonia), alcohol with six (homicide, drug poisoning, suicide, stroke, pneumonia, cirrhosis), drug use with six (AIDS, homicide, drug poisoning, suicide, stroke, cirrhosis), and diet/physical inactivity with three (ischemic heart disease, stroke, prostate cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $19.3 \%$ of the 16712 expected years of life lost from all causes. Ischemic heart disease, lung cancer ( $7.4 \%$ ), and stroke ( $7.1 \%$ ) accounted for a third of all expected years of life lost. The most premature causes were AIDS and suicide, causing an average of 45 and 33 expected years of life lost per death, respectively. Injuries were the tenth leading cause of death (suicide). Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, chronic obstructive pulmonary disease, colorectal cancer), alcohol with five (stroke, pneumonia, breast and colorectal cancer, suicide), drug use with three (stroke, AIDS, suicide), and diet/physical inactivity with four (ischemic heart disease, stroke, breast cancer, diabetes mellitus).

### 3.7.11 Parkside (94116)

Figure 38: Leading causes of death for Parkside (94116) males (top) and females (bottom), 1990-1995. For all causes, there were 1500 male deaths (SEYLL $=28465$ years) and 1479 female deaths (SEYLL $=18227$ years). The 1990 Census population estimate was 39424 ( $5.4 \%$ of total population).

Among males in 94116: Ischemic heart disease the leading cause of death, representing $19.1 \%$ of the 28465 expected years of life lost from all causes. Ischemic heart disease (19.1\%), AIDS (18.2\%), lung cancer ( $6.1 \%$ ), and stroke ( $5.0 \%$ ) accounted for $48 \%$ of all expected years of life lost. The most premature causes were AIDS, drug poisoning, and suicide, causing an average of 44,44 and 32 expected years of life lost per death, respectively. Injuries were the fifth and sixth leading causes of death. Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, colorectal cancer, chronic obstructive pulmonary disease, pneumonia), alcohol with six (stroke, drug poisoning, suicide, colorectal cancer, pneumonia, cardiomyopathy), drug use with five (AIDS, stroke, drug poisoning, suicide, cardiomyopathy), and diet/physical inactivity with four (ischemic heart disease, stroke, colorectal cancer, cardiomyopathy).

Among females: Ischemic heart disease was the leading cause of death, representing $19.5 \%$ of the 18227 expected years of life lost from all causes. Ischemic heart disease, stroke ( $8.6 \%$ ), and lung cancer ( $6.3 \%$ ) accounted for $34 \%$ of all expected years of life lost. The most premature cause was AIDS, causing an average of 45 expected years of life lost per death. There were no injury causes among the ten leading causes of death. Tobacco was associated with six leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, chronic obstructive pulmonary disease, colorectal cancer), alcohol with four (stroke, breast cancer, pneumonia, colorectal cancer), drug use with two (stroke, AIDS), and diet/physical inactivity with four (ischemic heart disease, stroke, breast and colorectal cancer).

### 3.7.12 Haight-Ashbury (94117)

Figure 39: Leading causes of death for Haight-Ashbury (94117) males (top) and females (bottom), 1990-1995. For all causes, there were 1528 male deaths (SEYLL $=53320$ years) and 642 female deaths $(S E Y L L=11405$ years). The 1990 Census population estimate was 38311 ( $5.3 \%$ of total population).

Among males in 94117: AIDS was the leading cause of death, representing $61.8 \%$ of the 53320 expected years of life lost from all causes. AIDS, ischemic heart disease ( $6.1 \%$ ), suicide ( $3.2 \%$ ), and drug poisoning ( $2.6 \%$ ) accounted for $74 \%$ of all expected years of life lost. The most premature causes were drug poisoning, homicide, suicide, and AIDS, causing an average of 47, 47, 46, and 44 expected years of life lost per death, respectively. Injuries were the third, fourth, and fifth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, pneumonia, stroke), alcohol with six (suicide, drug poisoning, homicide, cirrhosis, pneumonia, stroke), drug use with six (AIDS, suicide, drug poisoning, homicide, cirrhosis, stroke) and diet/physical inactivity with three (ischemic heart disease, stroke, prostate cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $15.9 \%$ of the 11405 expected years of life lost from all causes. Ischemic heart disease, stroke ( $5.9 \%$ ), lung cancer ( $5.4 \%$ ), breast cancer ( $5.2 \%$ ), and poisoning ( $5.2 \%$ ) accounted for $38 \%$ of all expected years of life lost. The most premature causes were MV-traffic, drug poisoning, and suicide, causing an average of 54,45 , and 44 expected years of life lost per death, respectively. Injuries were the fifth, seventh, and tenth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, chronic obstructive pulmonary disease, pneumonia), alcohol with seven (stroke, breast cancer, drug poisoning, suicide, cirrhosis, pneumonia, MV-traffic), drug use with five (stroke, drug poisoning, suicide, cirrhosis, MV-traffic), and diet/physical inactivity with three (ischemic heart disease, stroke, breast cancer).

### 3.7.13 Inner Richmond (94118)

Figure 40: Leading causes of death for Inner Richmond (94118) males (top) and females (bottom), 1990-1995. For all causes, there were 929 male deaths (SEYLL $=19146$ years) and 1001 female deaths $(S E Y L L=12345$ years). The 1990 Census population estimate was 38328 ( $5.3 \%$ of total population).

Among males in 94118: AIDS was the leading cause of death, representing $17.9 \%$ of the 19146 standard expected years of life lost from all causes. AIDS and ischemic heart disease (17.6\%) accounted for $35 \%$ of all expected years of life lost. The most premature causes were homicide, drug poisoning, MV-traffic, AIDS, and suicide, causing an average of $54,44,44,43$, and 42 expected years of life lost per death, respectively. Injuries were the fifth, seventh, eighth, and tenth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, chronic obstructive pulmonary disease, pneumonia), alcohol with six (stroke, suicide, drug poisoning, MVtraffic, pneumonia, homicide), drug use with six (AIDS, stroke, suicide, drug poisoning, MV-traffic, homicide) and diet/physical inactivity with two (ischemic heart disease, stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $17.8 \%$ of the 12345 standard expected years of life lost from all causes. Ischemic heart disease, stroke (8.9\%), lung cancer ( $7.4 \%$ ), and breast cancer ( $7.2 \%$ ) accounted for $41 \%$ of all expected years of life lost. The most premature causes were congenital anomalies and MV-traffic, causing an average of 54 and 42 expected years of life lost per death, respectively. Injuries were the sixth leading cause of death (MV-traffic). Tobacco was associated with four leading causes (ischemic heart disease, stroke, pneumonia, chronic obstructive pulmonary disease), alcohol with four (stroke, breast cancer, pneumonia, MV-traffic), drug use with two (stroke, MV-traffic), and diet/physical inactivity with three (ischemic heart disease, stroke, breast cancer).

### 3.7.14 Outer Richmond (94121)

Figure 41: Leading causes of death for Outer Richmond (94121) males (top) and females (bottom), 1990-1995. For all causes, there were 1133 male deaths (SEYLL $=22179$ years) and 1150 female deaths $(\mathrm{SEYLL}=14642$ years). The 1990 Census population estimate was 40559 ( $5.6 \%$ of total population).

Among males in 94121: Ischemic heart disease was the leading cause of death, representing $18.1 \%$ of the 22179 expected years of life lost from all causes. Ischemic heart disease, AIDS (17.1\%), lung cancer ( $6.2 \%$ ), stroke ( $4.8 \%$ ), and suicide ( $4 \%$ ) accounted for one-half of all expected years of life lost. The most premature causes were AIDS, homicide, and suicide, causing an average of 44, 43, and 40 expected years of life lost per death, respectively. Injuries were the fifth and ninth leading causes of death. Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, colorectal cancer, chronic obstructive pulmonary disease), alcohol with six (stroke, suicide, pneumonia, colorectal and liver cancer, homicide), drug use with four (AIDS, stroke, suicide, homicide) and diet/physical inactivity with three (ischemic heart disease, stroke, colorectal cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $19.6 \%$ of the 14642 expected years of life lost from all causes. Ischemic heart disease, stroke ( $8.5 \%$ ), breast cancer $(7.2 \%)$, and lung cancer ( $6.5 \%$ ) accounted for $42 \%$ of all expected years of life lost. The most premature cause was suicide, causing an average of 34 expected years of life lost per death. Injuries were the fifth leading cause of death (suicide). Tobacco was associated with six leading causes (ischemic heart disease, stroke, lung cancer, chronic obstructive pulmonary disease, colorectal cancer, pneumonia), alcohol with five (stroke, breast cancer, suicide, colorectal cancer, pneumonia) drug use with two (stroke, suicide), and diet/physical inactivity with five (ischemic heart disease, stroke, breast and colorectal cancer, diabetes mellitus).

### 3.7.15 Sunset (94122)

Figure 42: Leading causes of death for Sunset (94122) males (top) and females (bottom), 1990-1995. For all causes, there were 1493 male deaths (SEYLL $=28770$ years) and 1544 female deaths (SEYLL $=19954$ years). The 1990 Census population estimate was 52828 ( $7.3 \%$ of total population).

Among males in 94122: Ischemic heart disease was the leading cause of death, representing $16.6 \%$ of the 28770 expected years of life lost from all causes. Ischemic heart disease, AIDS ( $15.9 \%$ ), and lung cancer ( $6 \%$ ) accounted for $38 \%$ of all expected years of life lost. The most premature causes were AIDS, suicide, cirrhosis, and MV-traffic, causing an average of 43, 38, 36, and 34 expected years of life lost per death, respectively. Injuries were the fifth and sixth leading causes of death. Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, colorectal cancer, chronic obstructive pulmonary disease), alcohol with six (stroke, MV-traffic, suicide, pneumonia, colorectal cancer, cirrhosis), drug use with four (AIDS, stroke, suicide, cirrhosis) and diet/physical inactivity with three (ischemic heart disease, stroke, colorectal cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $20.9 \%$ of the 19954 expected years of life lost from all causes. Ischemic heart disease, stroke ( $7.3 \%$ ), lung cancer ( $5.9 \%$ ), and breast cancer ( $5.5 \%$ ) accounted for $40 \%$ of all expected years of life lost. The most premature cause was suicide, causing an average of 31 expected years of life lost per death. Injuries were the eighth leading cause of death (suicide). Tobacco was associated with six leading causes (ischemic heart disease, stroke, lung cancer, chronic obstructive pulmonary disease, pneumonia,colorectal cancer), alcohol with five (stroke, breast cancer, pneumonia, colorectal cancer, suicide) drug use with two (stroke and suicide), and diet/physical inactivity with four (ischemic heart disease, stroke, breast and colorectal cancer).

### 3.7.16 Marina (94123)

Figure 43: Leading causes of death for Marina (94123) males (top) and females (bottom), 1990-1995. For all causes, there were 552 male deaths (SEYLL $=10151$ years) and 674 female deaths (SEYLL $=$ 7603 years). The 1990 Census population estimate was 23297 ( $3.2 \%$ of total population).

Among males in 94123: AIDS was the leading cause of death, representing $23.4 \%$ of the 10151 expected years of life lost from all causes. AIDS and ischemic heart disease ( $21.5 \%$ ) accounted for $45 \%$ of all expected years of life lost. The most premature causes were MV-traffic and AIDS, causing an average of 54 and 42 expected years of life lost per death, respectively. Injuries were the fifth, seventh, and ninth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, colorectal cancer), alcohol with six (stroke, suicide, pneumonia, MV-traffic, colorectal cancer, falls), drug use with five (AIDS, stroke, suicide, MV-traffic, falls), and diet/physical inactivity with three (ischemic heart disease, stroke, colorectal cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $21.3 \%$ of the 7603 expected years of life lost from all causes. Ischemic heart disease, stroke ( $8.7 \%$ ), lung cancer ( $7.3 \%$ ), and breast cancer ( $7 \%$ ) accounted for $44 \%$ of all expected year of life lost. The most premature cause was MV-traffic, causing an average of 38 expected years of life lost per death. Injury was the seventh leading cause of death (MV-traffic). Tobacco was associated with six leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, chronic obstructive pulmonary disease, pancreas cancer), alcohol with five (stroke, breast cancer, pneumonia, MV-traffic, colorectal cancer), drug use with two (stroke and MV-traffic), and diet/physical inactivity with four (ischemic heart disease, stroke, breast and colorectal cancer).

### 3.7.17 Bayview-Hunters Point (94124)

Figure 44: Leading causes of death for Bayview-Hunters Point (94124) males (top) and females (bottom), 1990-1995. For all causes, there were 1012 male deaths (SEYLL $=28754$ years) and 796 female deaths (SEYLL $=17071$ years). The 1990 Census population estimate was 27105 (3.7\% of total population).

Among males in 94124: Homicide was the leading cause of death, representing $14.5 \%$ of the 28754 expected years of life lost from all causes, followed by AIDS (13.6\%) and ischemic heart disease (12\%). The most premature causes were sudden infant death syndrome (SIDS), homicide, MV-traffic, suicide, AIDS, and drug poisoning, causing an average of $83,59,54,50,44$, and 40 expected years of life lost per death, respectively. Injuries were the first, seventh, eighth, and ninth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, SIDS, pneumonia), alcohol with six (homicide, stroke, drug poisoning, MV-traffic, suicide, pneumonia), drug use with six (homicide, AIDS, stroke, drug poisoning, MV-traffic, suicide), and diet/physical inactivity with two (ischemic heart disease and stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $15.9 \%$ of the 17071 expected years of life lost from all causes, followed by breast cancer $(6.4 \%)$, stroke $(5.2 \%)$, and AIDS ( $5.1 \%$ ). The most premature causes were SIDS, birth asphyxia \& trauma, homicide, and drug poisoning, causing an average of $82,82,53,51$, and 46 expected years of life lost per death, respectively. Injuries were the sixth, eighth, and tenth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, stroke, lung cancer, SIDS), alcohol with four (breast cancer, stroke, homicide, drug poisoning), drug use with four (AIDS, stroke, homicide, drug poisoning), and diet/physical inactivity with four (ischemic heart disease, breast cancer, stroke, diabetes mellitus).

### 3.7.18 St. Francis Wood, Miraloma/Seaside (94127)

Figure 45: Leading causes of death forSt. Francis Wood, Miraloma/Seaside (94127) males (top) and females (bottom), 1990-1995. For all causes, there were 608 male deaths (SEYLL $=12511$ years) and 638 female deaths (SEYLL $=8094$ years). The 1990 Census population estimate was 17837 (2.5\% of total population).

Among males in 94127: AIDS was the leading cause of death, representing $26.7 \%$ of the 12511 expected years of life lost from all causes. AIDS, ischemic heart disease (16.9\%), and lung cancer (6.3\%) accounted for one-half of all expected years of life lost. The most premature causes were congenital anomalies, AIDS, drug poisoning, and suicide, causing an average of $82,44,39$, and 34 expected years of life lost per death, respectively. Injuries were the eighth and ninth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, stroke, chronic obstructive pulmonary disease), alcohol with four (stroke, prostate cancer, suicide, drug poisoning), drug use with four (AIDS, stroke, suicide, drug poisoning) and diet/physical inactivity with three (ischemic heart disease, stroke, prostate cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $17.3 \%$ of the 8094 expected years of life lost from all causes. Ischemic heart disease, lung cancer ( $11.1 \%$ ), stroke ( $7.2 \%$ ), and breast cancer ( $6.7 \%$ ) accounted for $42 \%$ of all expected years of life lost . The most premature cause was congenital anomalies, causing an average of 54 expected years of life lost per death. Injuries were the ninth leading causes of death (suicide). Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, colorectal cancer, chronic obstructive pulmonary disease), alcohol with five (stroke, breast cancer, pneumonia, colorectal cancer, suicide), drug use with two (stroke and suicide), and diet/physical inactivity with four (ischemic heart disease, stroke, breast and colorectal cancer).

### 3.7.19 Twin Peaks-Glen Park (94131)

Figure 46: Leading causes of death for Twin Peaks-Glen Park (94131) males (top) and females (bottom), 1990-1995. For all causes, there were 1095 male deaths (SEYLL $=32737$ years) and 524 female deaths (SEYLL $=8230$ years). The 1990 Census population estimate was 30625 ( $4.2 \%$ of total population).

Among males in 94131: AIDS was the leading cause of death, representing $56.8 \%$ of the 32737 expected years of life lost from all causes. AIDS and ischemic heart disease (7.2\%) accounted for $64 \%$ of all expected years of life lost. The most premature causes were drug poisoning, homicide, and AIDS, which caused an average of 53,47 , and 43 expected years of life lost per death, respectively. Injuries were the third, ninth, and tenth leading causes of death. Tobacco was associated with four leading causes (ischemic heart disease, lung cancer, pneumonia, stroke), alcohol with six (suicide, pneumonia, cirrhosis, stroke, homicide, drug poisoning), drug use with six (AIDS, suicide, stroke, cirrhosis, homicide, drug poisoning) and diet/physical inactivity with two (ischemic heart disease and stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $18 \%$ of the 8230 expected years of life lost from all causes. Ischemic heart disease and lung cancer (9.2\%) accounted for $27 \%$ of all expected years of life lost. The most premature cause was suicide, causing an average of 45 expected years of life lost per death. Injuries were the fifth leading causes of death (suicide). Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, chronic obstructive pulmonary disease, pneumonia, colorectal cancer), alcohol with six (breast cancer, stroke, suicide, pneumonia, colorectal cancer, cirrhosis), drug use with three (stroke, suicide, cirrhosis), and diet/physical inactivity with five (ischemic heart disease, breast cancer, stroke, uterine and colorectal cancer).

### 3.7.20 Lake Merced (94132)

Figure 47: Leading causes of death for Lake Merced (94132) males (top) and females (bottom), 19901995. For all causes, there were 819 male deaths (SEYLL $=15138$ years) and 880 female deaths $(S E Y L L=11291$ years $)$. The 1990 Census population estimate was 23667 ( $3.3 \%$ of total population).

Among males in 94132: Ischemic heart disease was the leading cause of death, representing $20 \%$ of the 15138 expected years of life lost from all causes. Ischemic heart disease and AIDS ( $14.2 \%$ ) accounted for more than one-third of all expected years of life lost. The most premature causes were homicide, AIDS, and suicide, causing an average of 50,44 , and 35 expected years of life lost per death, respectively. Injuries were the fifth and seventh leading causes of death. Tobacco was associated with six leading causes (ischemic heart disease, lung cancer, stroke, pneumonia, colorectal cancer, chronic obstructive pulmonary disease), alcohol with six (stroke, homicide, pneumonia, suicide, colorectal cancer, cirrhosis), drug use with five (AIDS, stroke, homicide, suicide, cirrhosis) and diet/physical inactivity with three (ischemic heart disease, stoke, colorectal cancer).

Among females: Ischemic heart disease was the leading cause of death, representing $21.2 \%$ of the 11291 expected years of life lost from all causes. Ischemic heart disease, stroke ( $8.5 \%$ ), breast cancer $(7.2 \%)$, and lung cancer ( $6.7 \%$ ) accounted for $44 \%$ of all expected years of life lost. The most premature causes were AIDS and MV-traffic, causing an average of 46 and 30 expected years of life lost per death, respectively. Injuries were the tenth leading causes of death (MV-traffic). Tobacco was associated with seven leading causes (ischemic heart disease, stroke, lung cancer, colorectal cancer, pneumonia, chronic obstructive pulmonary disease, pancreas cancer), alcohol with five (stroke, breast cancer, colorectal cancer, pneumonia, MV-traffic), drug use with three (stroke, AIDS, MV-traffic), and diet/physical inactivity with four (ischemic heart disease, stroke, breast and colorectal cancer).

### 3.7.21 North Beach/Chinatown (94133)

Figure 48: Leading causes of death for North Beach/Chinatown (94133) males (top) and females (bottom), 1990-1995. For all causes, there were 926 male deaths (SEYLL $=16370$ years) and 877 female deaths (SEYLL = 10850 years). The 1990 Census population estimate was 27331 ( $3.8 \%$ of total population).

Among males in 94133: Ischemic heart disease was the leading cause of death, representing $20.8 \%$ of the 16370 expected years of life lost from all causes. Ischemic heart disease, AIDS (9.6\%), and lung cancer $(3.2 \%)$ accounted for one-third of all expected years of life lost. The most premature cause was AIDS, causing an average of 38 expected years of life lost per death. Injuries were the seventh and eighth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, lung cancer, stroke, chronic obstructive pulmonary disease pneumonia), alcohol with six (stroke, pneumonia, suicide, MV-traffic, cirrhosis, liver cancer), drug use with six (AIDS, stroke, suicide, MV-traffic, cirrhosis, liver cancer) and diet/ physical inactivity with three (ischemic heart disease, lung cancer, stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $19.2 \%$ of the 10850 expected years of life lost from all causes. Ischemic heart disease, stroke ( $10.5 \%$ ), and lung cancer (6.7\%) accounted for $36 \%$ of all expected years of life lost. The most premature cause was congenital anomalies, causing an average of 51 expected years of life lost per death. Injuries were the ninth leading cause of death (MV-traffic). Tobacco was associated with six leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, colorectal cancer, chronic obstructive pulmonary disease), alcohol with five (stroke, breast cancer, pneumonia, colorectal cancer, MV-traffic), drug use with two (stroke and MV-traffic), and diet/physical inactivity with six (ischemic heart disease, stroke, lung, breast, and colorectal cancer, diabetes mellitus).

### 3.7.22 Visitación Valley/Sunnydale (94134)

Figure 49: Leading causes of death for Visitacion Valley/Sunnydale (94134) males (top) and females (bottom), 1990-1995. For all causes, there were 926 male deaths (SEYLL $=22464$ years) and 781 female deaths (SEYLL = 14360 years). The 1990 Census population estimate was 34603 (4.8\% of total population).

Among males in 94134: Ischemic heart disease was the leading cause of death, representing $15.9 \%$ of the 22464 expected years of life lost from all causes. Ischemic heart disease, AIDS (10.5\%), and homicide ( $8.6 \%$ ) accounted for $35 \%$ of all expected years of life lost. The most premature causes were sudden infant death syndrome (SIDS), homicide, drug poisoning, and MV-traffic, causing an average of $82,57,48$, and 47 expected years of life lost per death, respectively. Injuries were the third, fifth, and seventh leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, SIDS, pneumonia), alcohol with six (homicide, stroke, MV-traffic, drug poisoning, pneumonia, cirrhosis), drug use with six (AIDS, homicide, stroke, MV-traffic, drug poisoning, cirrhosis) and diet/ physical inactivity with two (ischemic heart disease and stroke).

Among females: Ischemic heart disease was the leading cause of death, representing $15.6 \%$ of the 14360 expected years of life lost from all causes. Ischemic heart disease, stroke ( $7.3 \%$ ), and lung cancer (6\%) accounted for $29 \%$ of all expected years of life lost. The most premature causes were MV-traffic, homicide, drug poisoning, and AIDS, causing an average of 54, 52, 46, and 42 expected years of life lost per death, respectively. Injuries were the seventh, eighth, and ninth leading causes of death. Tobacco was associated with five leading causes (ischemic heart disease, stroke, lung cancer, pneumonia, chronic obstructive pulmonary disease), alcohol with six (stroke, breast cancer, pneumonia, MV-traffic, drug poisoning, homicide), drug use with five (stroke, AIDS, MV-traffic, drug poisoning, homicide), and diet/physical inactivity with three (ischemic heart disease, stroke, breast cancer).

## GLOSSARY

Age-adjusted death rate is a rate which accounts for differences in age distributions across populations. The composite rate for a population resulting from applying its age-specific death rates to a population with the age distribution of a standard population (usually the 1940 U.S. standard million population). Age-adjusted rates based on the same standard population can be compared. Also called age-adjusted mortality rate.

Age distribution is the percentage of any given population in each age group (i.e., the percent of the population ages 5 to 14,15 to 24,25 to 44,65 or older, etc.). The age distributions of populations are important to consider when using rates because disease and death rates differ widely by age group. Age-adjusted death rates and life expectancies allow summary comparisons of the burden of mortality in populations with different age distributions.

Age-specific rate is a rate for a specified age group (e.g., the age-specific rate for ages 25 to 44 is the number of deaths in a given time period of people ages 25 to 44, divided by the number of people ages 25 to 44 in the population in that time period, times 1,000 [to get the rate per 1,000 population]). Age-adjusted rates are weighted averages of age-specific rates; as such, they may mask differences between populations in age-specific rates. Age-specific rates for the same age groups can be directly compared.

Average SEYLL is the average number of SEYLL (standard expected years of life lost) per death for a specified cause in a specified population. A rough measure of the degree of prematurity of deaths from given causes: the higher the average SEYLL, the younger the "average" age of death .

Causal risk factor, contributing factor, or determinant is a factor established as causing or contributing to the outcome or condition of interest (here, contributing to the specific cause of death).

Cause of death is a general name for the category of the ICD-9 code listed as the "underlying cause of death" on the death certificate.

Contributing factor, causal risk factor, or determinant is a factor established as causing or contributing to the outcome or condition of interest (here, contributing to the specific cause of death).

Crude death rate is a death rate calculated for a population, without accounting for its age distribution. Crude death rates provide a measure of overall burden of mortality in a population, but are misleading to compare across populations with different age distributions.

Death rate or mortality rate is the rate expressing proportion of a population dying from a specified cause or causes in a specified time period, usually expressed as deaths per year per 1,000 people in the population.

Demographics are the basic characteristics of populations, especially their distributions by age, sex, and ethnicity. Demographic characteristics are especially important to consider in population health assessments because they all reflect differences in rates of health conditions, exposure to determinants of health conditions, and health practices including use of health services.

Determinant, contributing factor or causal risk factor is a factor that can cause a particular outcome (e.g., smoking is a determinant of lung cancer, COPD, fires, etc.).

ICD-9 International Classification of Diseases, 9th edition is an internationally used method for classifying and coding specific conditions and groups of conditions.

Intentional injury is an injury intentionally inflicted on oneself or others. The main mortality causes are suicide, homicide, and legal intervention.

Life expectancy is the average number of years an individual is expected to live if current agespecific mortality rates continue to apply. Often reported as life expectancy at birth, but can apply to life expectancy at any given age. An overall measure of a population's current total mortality burden.

Morbidity is disease or injury, any departure from a state of physiological or psychological wellbeing.

Mortality is death.

Mortality rate, death rate is the number of deaths in a given population in a given time period, usually expressed as deaths per year per 1,000 people in the population (e.g., mortality rate for a population of 2,000 in which 50 deaths occur in one year is 25 ).

Neighborhood for this study San Francisco was defined geographically by U.S. Postal ZIP codes; these areas and the names of local neighborhoods roughly contained in the ZIP codes are shown in Table 46, p. 81.

Population attributable fraction is a measure of the amount of a disease or injury in a population that is attributed to exposure to a particular factor. The proportion or percentage of cases of a health condition in a population that can be said to be due to exposure to a particular factor which can cause that condition (e.g., over $85 \%$ of lung cancers have been attributed to exposure to tobacco smoke, so the population attributable fraction of tobacco smoking for lung cancer is over 85).

Prevention attribution matrix is our table for classifying the relationships between a set of conditions (e.g., leading causes of death) and determinants whose control could prevent a portion (up to the population attributable fraction) of those conditions from occurring (see Tables 5-7, pp. 23-25).

Rate is number of events of interest occurring in a defined population during a specified time period, usually expressed per specified unit size of the population involved (e.g., death rate usually reported as numbers of deaths in a given population in a given year per 1,000 people in that population at midyear).

Rate ratio is the ratio of two rates. For a ratio of $A / B$, the risk of $A$ is compared to the risk of $B$; $B$ is used as the standard of comparison.

Risk factor is an attribute or exposure associated with increased risk of death or morbidity.

SEYLL is standard expected years of life lost.

Specific cause of death generally refers to a relatively narrow category of the ICD-9 code listed as the "underlying cause of death" on the death certificate. In this study, cause of death categories designated as specific enough to be useful for guiding prevention efforts, and eligible to appear in a leading cause of death ranking (see Table 2, p. 15).

Standard expected years of life lost (SEYLL) When a person dies the SEYLL is the years of life lost based on the life expectancy for a person of that age. For a population, SEYLL is the sum, for all persons dying from a particular cause, of the years they would have lived if they had experienced a normal life expectancy. A measure of the relative impact of the various diseases and lethal forces on a society.

Standard population is a population whose age distribution is used as a standard for calculating age-adjusted rates. The U.S. standard for decades has been the 1940 U.S. population; next year it will change to the U.S. 2000 population (which has a much higher proportion of older people than the 1940 population). Only rates standardized to the same standard population can be directly compared.

Standardization is a weighted averaging according to a standard distribution. Age standardization involves calculating rates based on a standard population's age distribution; rates so calculated are called age-adjusted rates.
